Introduction

Why do I write this book? Are there not enough information available? Short answer: Yes there are! But have you found your desired information in time? Some weeks ago I was thinking about how this batch mode works in CLRMAME again. Did it use several time before but forgotten how it works. I had this information seen in a forum but where? This was the time when I was thinking about this guide and it would be helpful also for others. A guide that covers the main topics. Give an answer to many questions. I hope this guide will help some users to get into compiling, using CLRMAME for keeping up their sets and having fun as much I have.

As you may have notice English is not my mother language, excuse some wrong expressions/word that I'm using. I hope you will enjoy this guide as much as I have enjoyed it writing it :-)

The man behind this book

My first contact was at around 1999 with MAME. Never tough that I can play my loved Donkey Kong on a PC that I have spend so much time/coins some years ago on a real arcade machine. That was the time I started collecting everything for MAME. With no knowledge how does it work with ROMs I have completed my small set with run each game, see what was missing and tried to download somewhere those missing. It was a really adventure to go on with my set. Later I have burned my first “public” CD set for some friends (V0.59).

My knowledge was better with each version that followed. After some complete sets I have decided to help others as a “MAME burner”. This time frame was only short it was the time that available bandwidth has increased rapidly. My next step was offering my set on a private FTP. And with the help of torrentzip it was possible to share everything much quicker than downloading from my ftp. I have also done the MAMEtiles for some time (0.97-0.145) but after the loose of the domain MAMEtiles.com I have decided to step back from that project. I have still a FTP, co-assist at Retroroms.net and I am around a lot of time on IRC-channels as well.

Thanks goes to

I would like to thank everyone that I know. Especially MAMEdev team for the emulator. There are so many I should mentioned here, thank you all that made this guide possible.

Important Note

Do always a backup of your files. I have tested everything in my own environment but I can not give you 100% guarantee that nothing worse can happen!

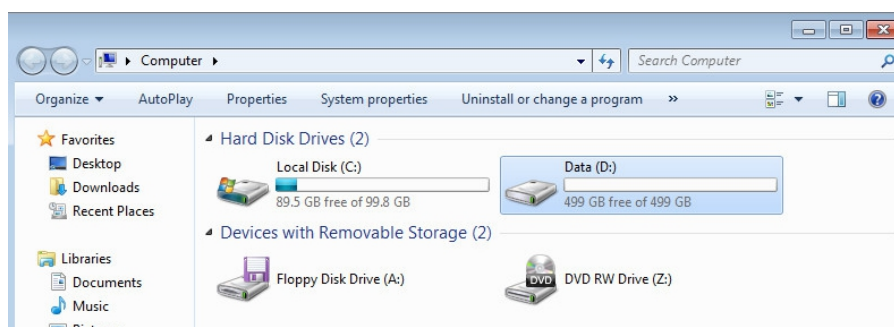

Chapter 1: Environment

In this guide I'm using a Windows 7 environment in a VM (VMWARE). It is not the best solution for gaming but for taking pictures for this guide it is perfect. Sometimes I'm switching to my “real” environment because I have there more items for covering a topic.

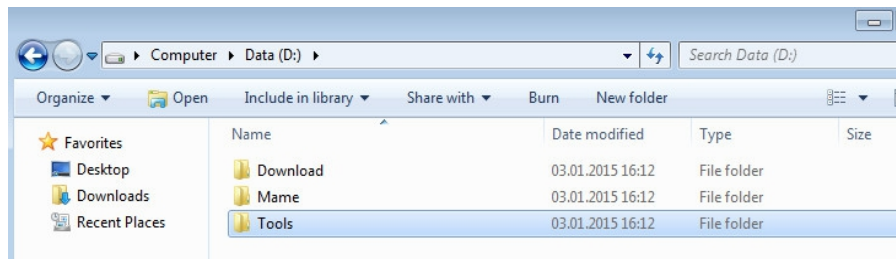

My environment, Windows 7 64.bit

Installed two discs in my environment, one system drive and another for my emulator stuff. All emulator related stuff is on my D-drive.

I have created the following folder structure on the data disc.

This folder structure will grow in the future if you plan to have more emulators than MAME/MESS.

! Creating a folder structure helps you organizing your files.

Chapter 2: MAME

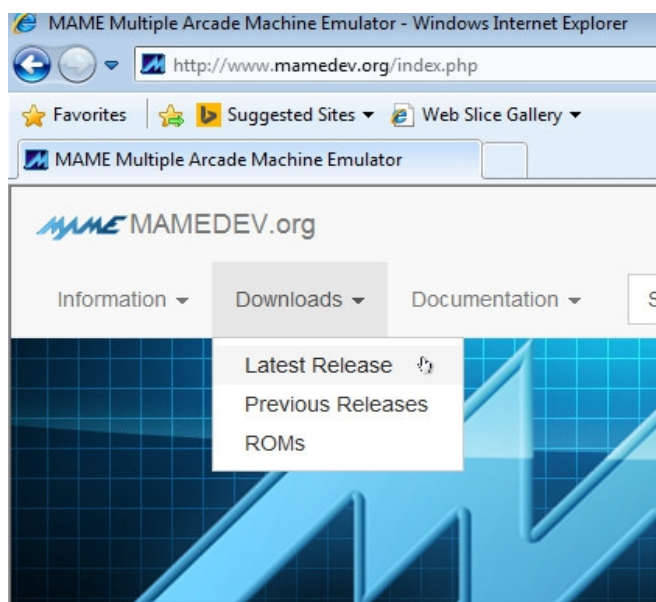

In this chapter we are looking into installing MAME (Multiple Arcade Machine Emulator) and how to have fun with it. This chapter does only covers the default official emulator.

Installing MAME (Windows)

We start a web browser and visit the MAMEdev website:

Under download we choose “latest release”

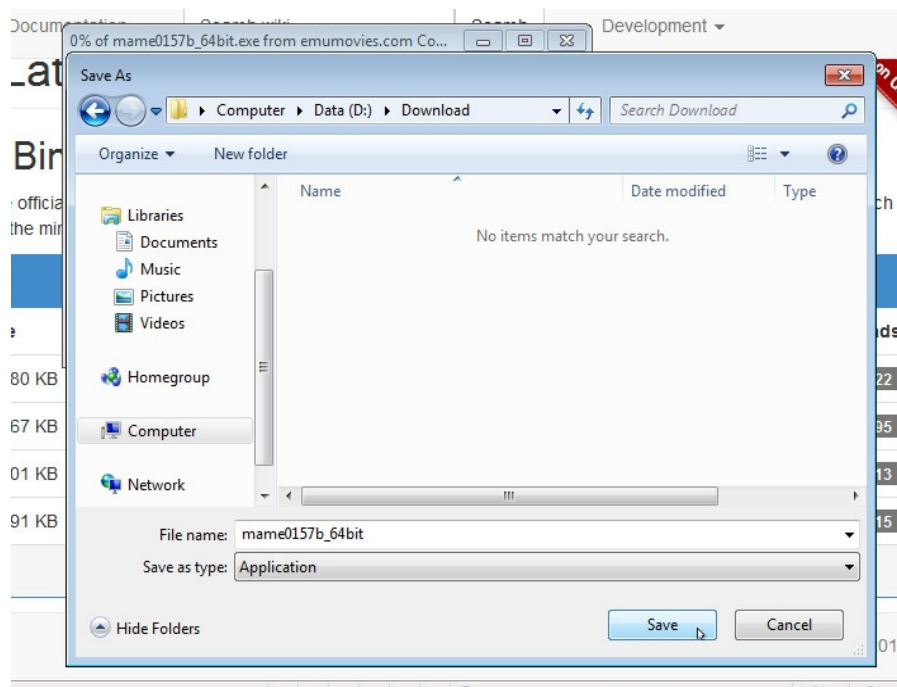

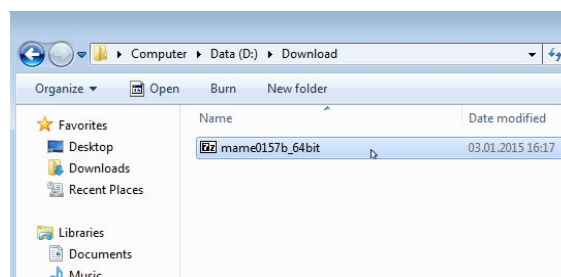

As we have a 64-bit version (Windows) we choose this file for downloading

MAME 0.157 Official Binaries		
File	Size	Description
mame0157b.exe	18680 KB	MAME 0.157 Windows command-line binaries.
mame0157b_i686.exe	19167 KB	MAME 0.157 Windows command-line binaries (i686 optimized).
mame0157b_64bit.exe	20101 KB	MAME 0.157 64-bit Windows command-line binaries.
mame0157b_debug.exe	20391 KB	MAME 0.157 Windows command-line binaries (debug build).

In the future we download everything in the same folder. I have created a folder “download” on my data drive and we save the file there.

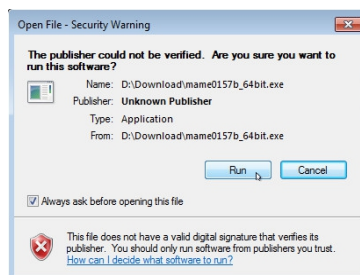

After the download has finished we have an executable file there.

We start the installation with double-clicking it

It is not really an installing program. It is only a self extracting executable.

We want to extract it to the folder “mame” on the data drive.

After the extracting we have a lot of files and folders in the “d:\mame”

The emulator itself is called “mame64.exe”.

! Remember we have installed now the 64-bit version.

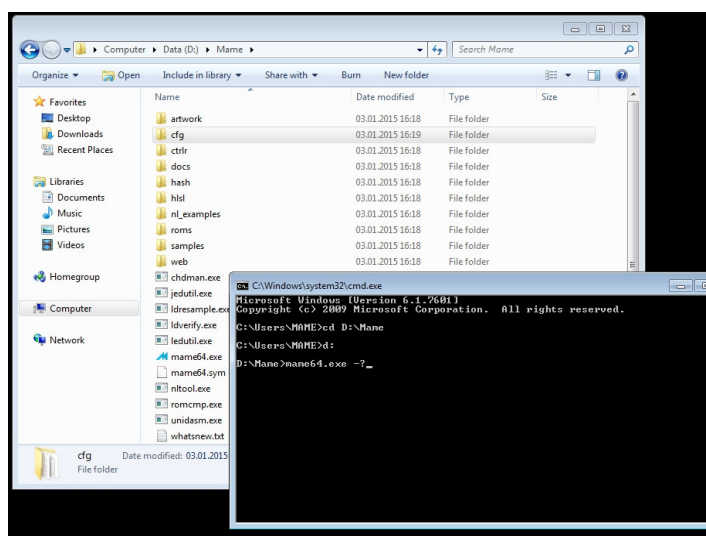

We start it and

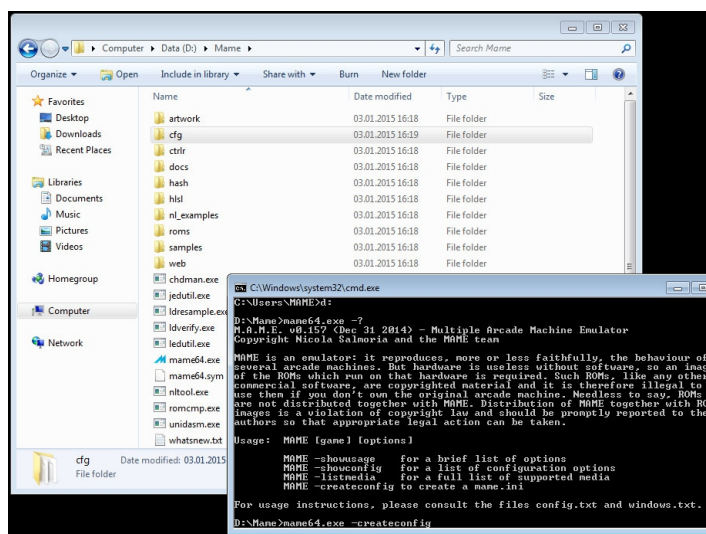

```
No games found. Please check the rompath specified in the mame.ini file.  
  
If this is your first time using MAME, please see the config.txt file in the docs directory  
for information on configuring MAME.  
  
Exit
```

..yes sure we have nothing else installed. The emulator has no games included.

As this emulator is a command-line tool we open a cmd-window and execute “mame64.exe -?”

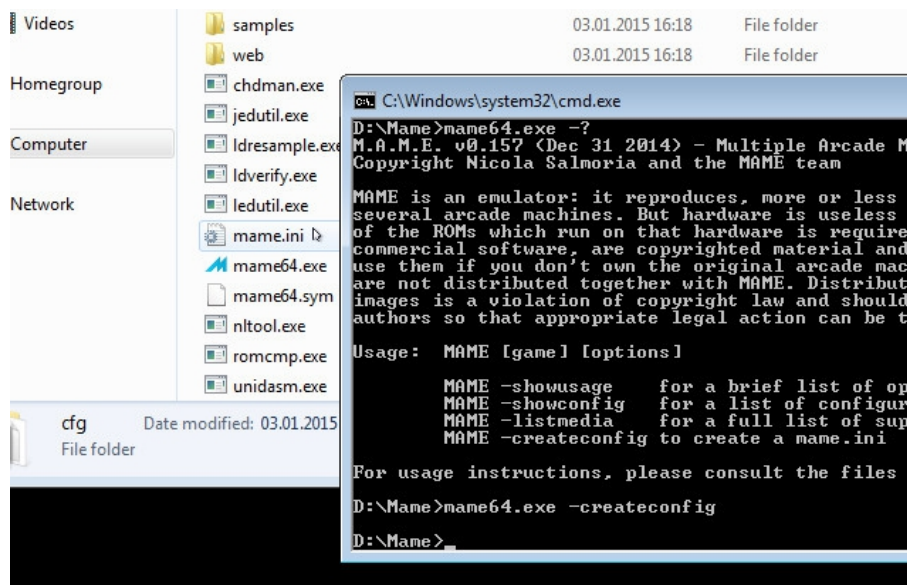

It shows use the version and some additional usage information

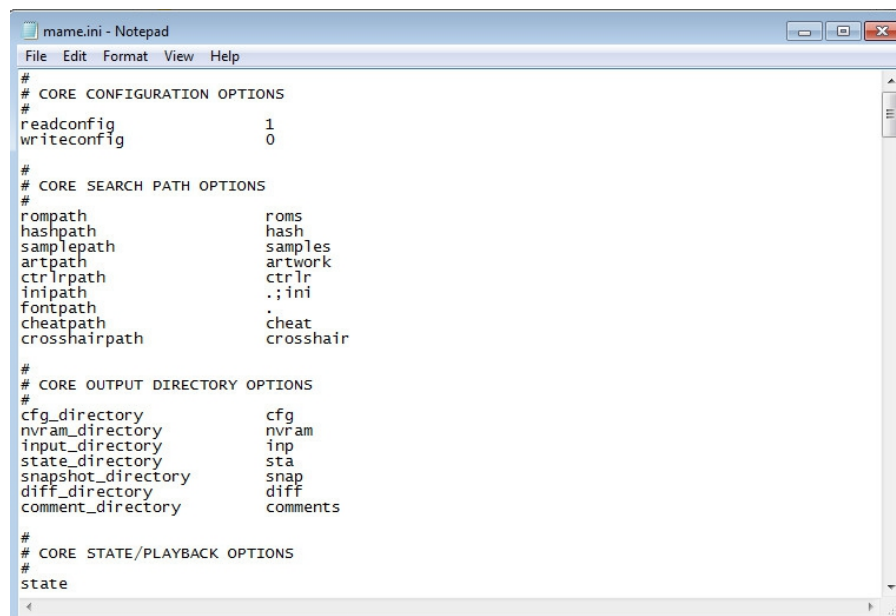

This emulator uses a ini-file to set some settings. At the beginning we must create this file “mame.ini” with the command “mame64.exe -createconfig”

We open this file with notepad

At the moment we do not change it, leave it as it is. There you could set some settings you want for each “run” of the emulator.

With the command “mame64.exe -showusage” ...

```
C:\Windows\system32\cmd.exe
D:\Mame>mame64.exe -showusage
```

... we get the information how we can use this emulator with all the options that are available.

```
C:\Windows\system32\cmd.exe
d:\Mame>mame64.exe -showusage
Usage: mame64 [game] [options]

Options:

## CORE CONFIGURATION OPTIONS
##
-readconfig          enable loading of configuration files
-writeconfig         writes configuration to (driver).ini on exit

## CORE SEARCH PATH OPTIONS
##
-rompath             path to ROMsets and hard disk images
-hashpath            path to hash files
-samplepath          path to samplesets
-artpath             path to artwork files
-ctrlrpath           path to controller definitions
-inipath             path to ini files
-fontpath            path to font files
-cheatpath           path to cheat files
-crosshairpath       path to crosshair files

## CORE OUTPUT DIRECTORY OPTIONS
##
-cfg_directory       directory to save configurations
-nvram_directory     directory to save nvram contents
-input_directory     directory to save input device logs
-state_directory     directory to save states
-snapshot_directory  directory to save screenshots
-diff_directory      directory to save hard drive image difference files
-comment_directory   directory to save debugger comments

## CORE STATE/PLAYBACK OPTIONS
##
```

As a test we want to start the emulator with my favourite game “Donkey Kong”

```
D:\Mame>mame64.exe dkong.zip -rompath D:\Mame\Roms\
```

We have not installed/downloaded this game and that's why we get an error complaining about missing files.

```
C:\Windows\system32\cmd.exe
MAME -showconfig for a list of configuration options
MAME -listmedia for a full list of supported media
MAME -createconfig to create a name.ini

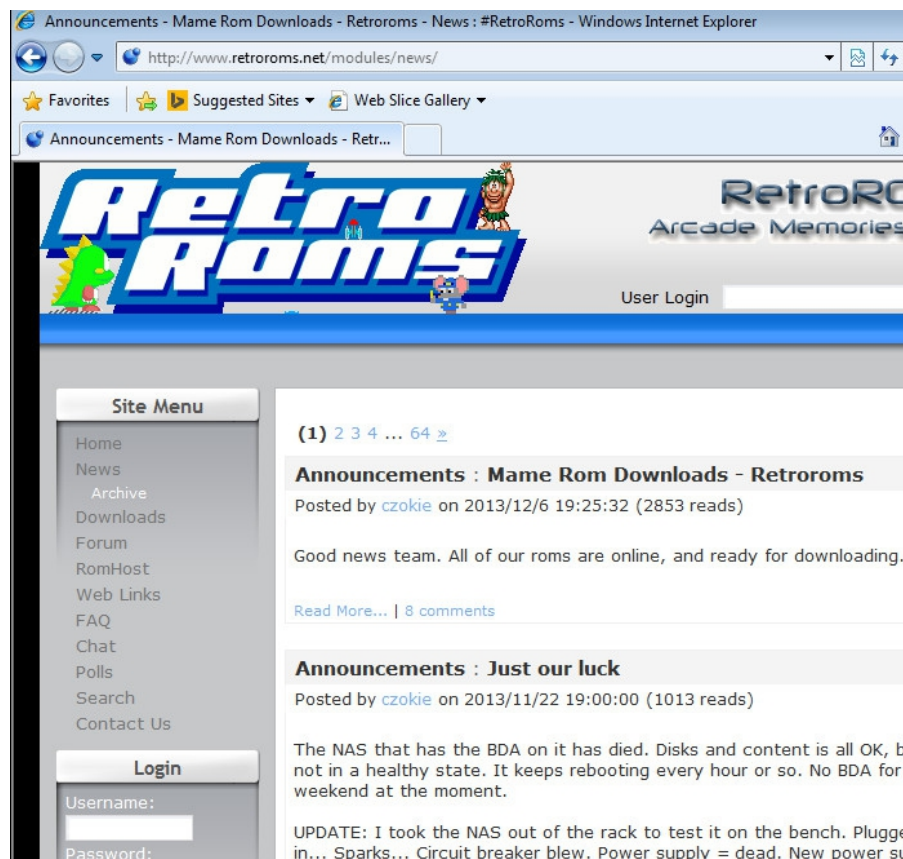

For usage instructions, please consult the files config.txt and windows.txt.

D:\Mame>mame64.exe dkong.zip -rompath D:\Mame\Roms\
c_5et.g.bin NOT FOUND (tried in dkong dkong)
c_5ct.g.bin NOT FOUND (tried in dkong dkong)
c_5bt.g.bin NOT FOUND (tried in dkong dkong)
c_5at.g.bin NOT FOUND (tried in dkong dkong)

c_2j.bpr NOT FOUND (tried in dkong dkong)
v_5e.bpr NOT FOUND (tried in dkong dkong)
FATALERROR: Required files are missing, the game cannot be run.

D:\Mame>
```

We want now test MAME if it does work or not with a game ;-)

Go to the Retroroms.net website, register there an account (free) and login with the new created account.

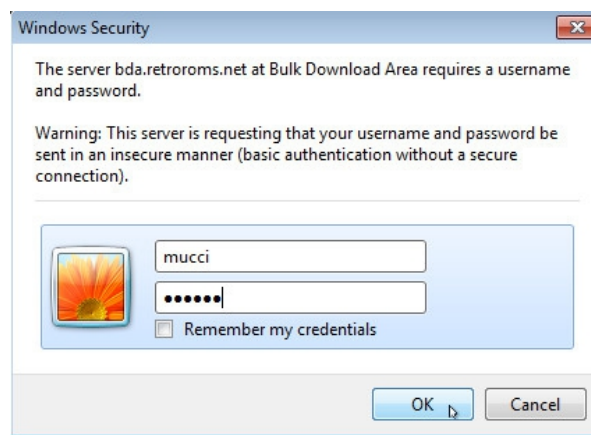

On the left panel choose “Downloads”

For downloading you need a registered account, fill in your details.

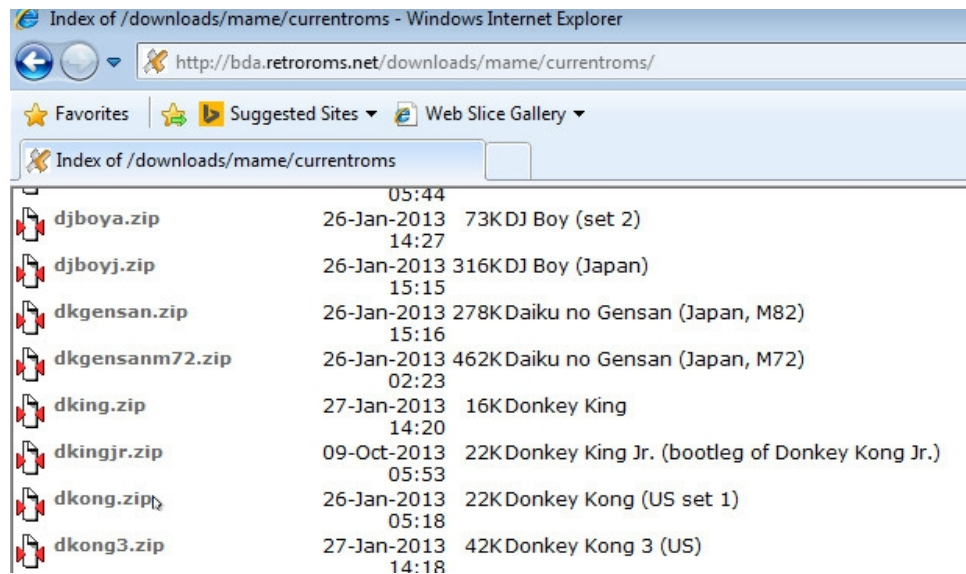

Go to the folder mame\currentroms ...

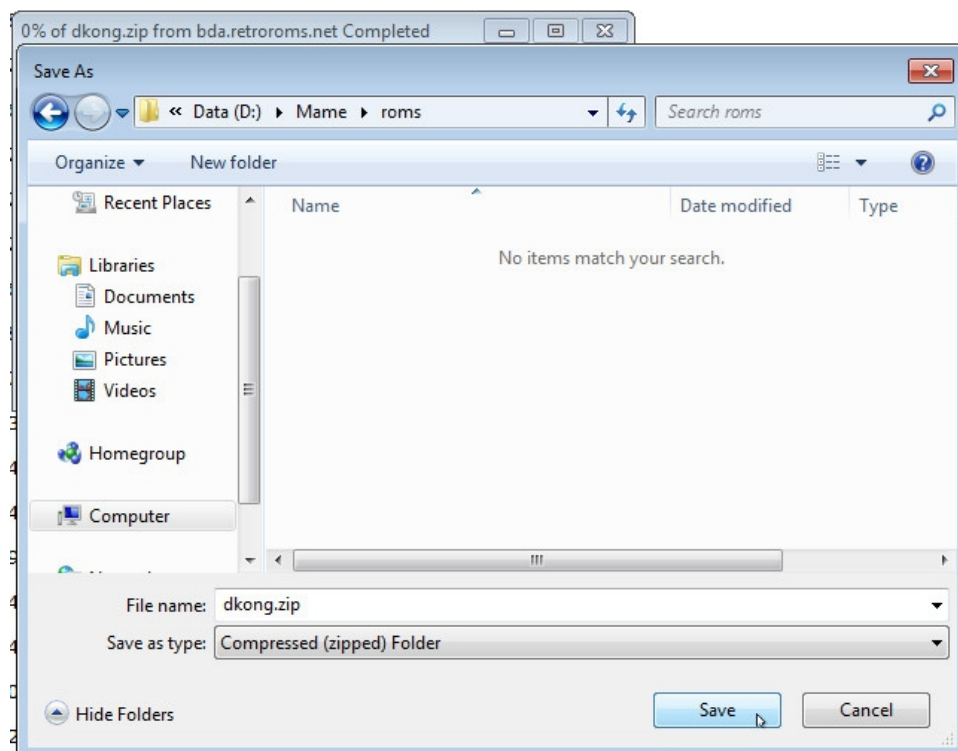

search for the file “dkong.zip”

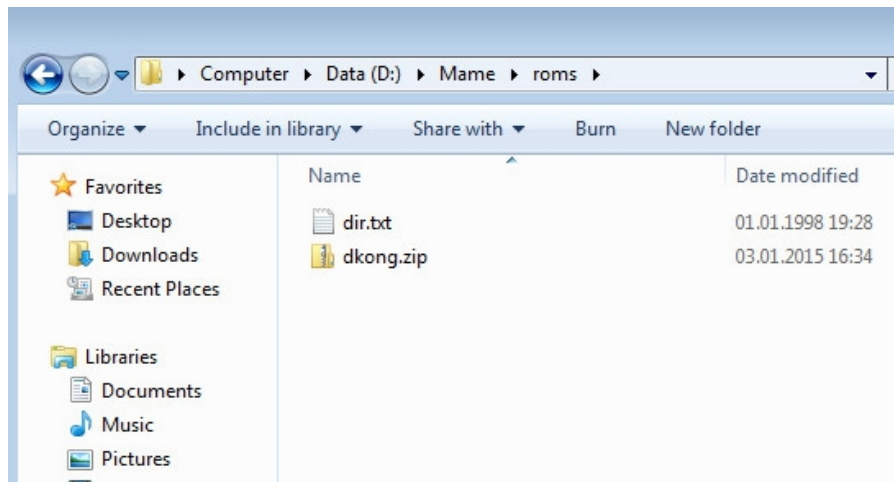

and download it directly in your mame\roms folder.

After the download the folder should look like that

! Do not extract this file. A lot of emulator does support zip-Files

We start the same command again in the cmd-window

```
C:\Windows\system32\cmd.exe

MAME -showconfig for a list of configuration options
MAME -listmedia for a full list of supported media
MAME -createconfig to create a mame.ini

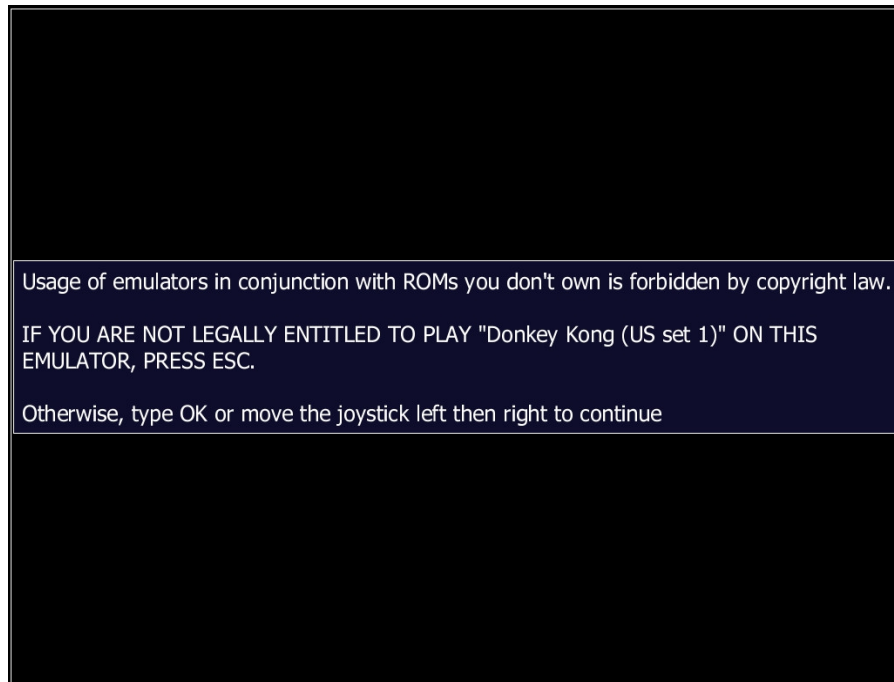

For usage instructions, please consult the files config.txt and windows.txt.

D:\Mame>mame64.exe dkong.zip -rompath D:\Mame\Roms\
c_5et_g.bin NOT FOUND <tried in dkong dkong>
c_5ct_g.bin NOT FOUND <tried in dkong dkong>

c-2j.bpr NOT FOUND <tried in dkong dkong>
v-5e.bpr NOT FOUND <tried in dkong dkong>
FATALERROR: Required files are missing, the game cannot be run.

D:\Mame>mame64.exe dkong.zip -rompath D:\Mame\Roms\
```

Ahhhhh no error this time. It displays us now a copyright message. Confirm this by typing “o” and “k” on the keyboard (yes sure we have the original arcade at home).

Now it displays us some information about the hardware of this original arcade cab

Press a key and now the game starts :-)

We can play now but for now we quit the game by pressing the “ESC” key

We are now ready to use that emulator with its default settings

Using MAME

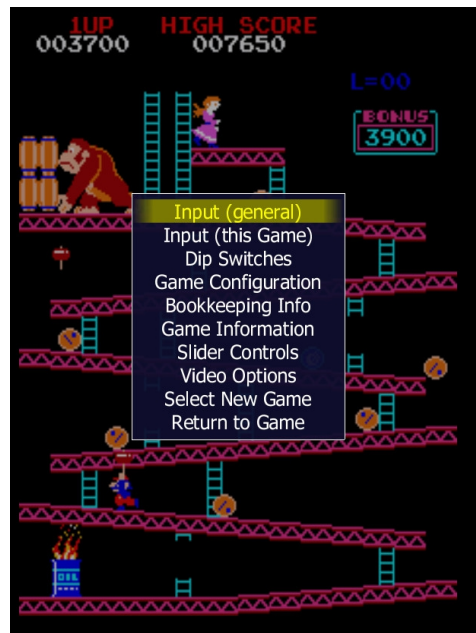

Let's start my favourite game again with MAME.

Everything you want to do in the configuration → pause the game with “p”

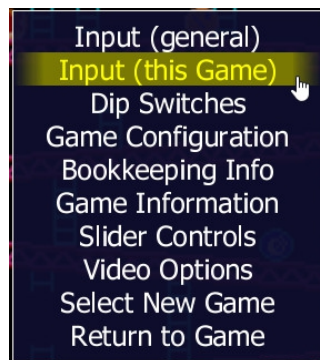

We can now go to eat something or we press the “tab” key. It will opens a menu.

Within this menu you use the “up” and “down” cursor for choosing and for changing the highlighted entry press “enter”.

Let's choose “Input (This Game)” and press “enter”

This are all available settings for this game (Donkey Kong). Here you can see which keys are used for moving Mario or let him jump. Can you remember what the first action is when you want to play it on an arcade cab? Yes right you have to insert a coin → Key “5” does simulate that. And for choosing a one player game you have to press “1”.

1 Player Start	1
2 Players Start	2
Coin 1	5
Service	F2
P1 Up	NACH-OBEN
P1 Down	NACH-UNTEN
P1 Left	NACH-LINKS
P1 Right	NACH-RECHTS
P1 Button 1	STRG or Mouse B0 or Gun 1 B0
P2 Up	R
P2 Down	F
P2 Left	D
P2 Right	G
P2 Button 1	A or Mouse B0 or Gun 2 B0
Return to Previous Menu	

If you want to change something → Highlight it and press “enter”. Now press the key that you want to have, that's it.

You can go back in the menu with the last entry or press “ESC”.

! Be aware that when you press too much “ESC” you will also quit the game.

Let's have a look at another entry. Choose “Dip Switches”

Input (general)
Input (this Game)
Dip Switches
Game Configuration
Bookkeeping Info
Game Information
Slider Controls
Video Options
Select New Game
Return to Game

Each game has different settings and as a real arcade game some of the settings are enabled with a Dip switch on the motherboard. This entry does simulate that. For Donkey Kong we can set for example how many lives you have at the start.

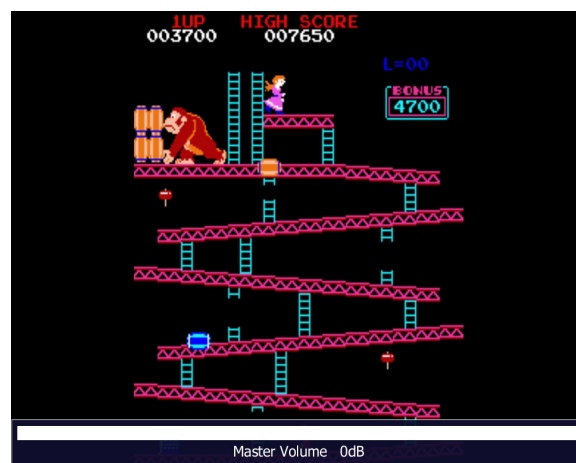

There are other items you can change for example Video options. Look around and see what is available. Normally you don't have to change it.

Let's go back to the game. Choose "Return to game " or press "ESC".

With the key "\$" you can set the volume (use the cursor keys). Press again "\$" or use "ESC" for leaving this option.

As we have seen in the menu insert coin is simulated with the key "5". Lets try it several time ...and yes you have now 15 credits ;-)

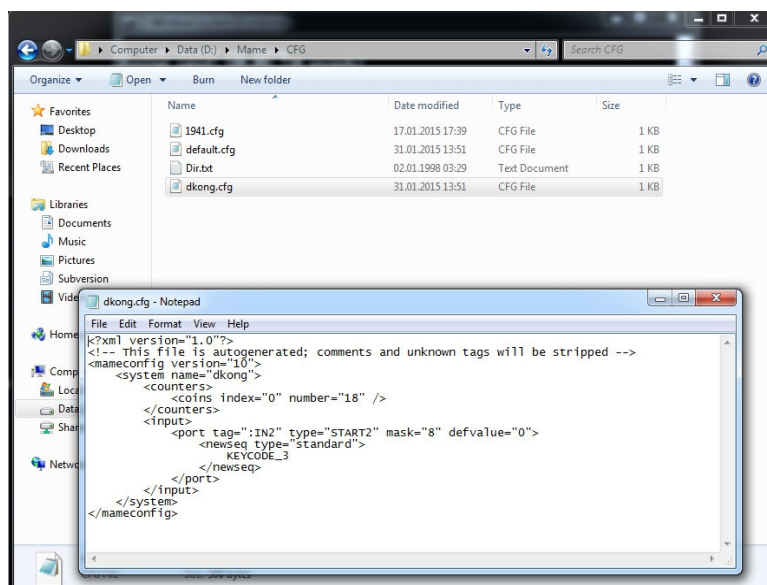

What's the next key you must use? Yeah right the key “1” is for a single player. After pressing “1” the game will start and you can move Mario aroundforgotten the keys you must use? Pause the game with “p” and hit the “Tab” key for entering the menu and look in “Input (this game)” what is defined.

Yeah after you have lost all your lives quit the game with “ESC”. The settings we have changed in the menu is saved to a cfg-file in a folder called Mame\cfg. There is now a cfg-file for the game “dkong”. It contains the setting we have changed. If you have changed a lot and can't remember all the default settings → delete this cfg-file and you're fine.

MAME/MESS The Guide

By the way the MAME folder structure is like that:

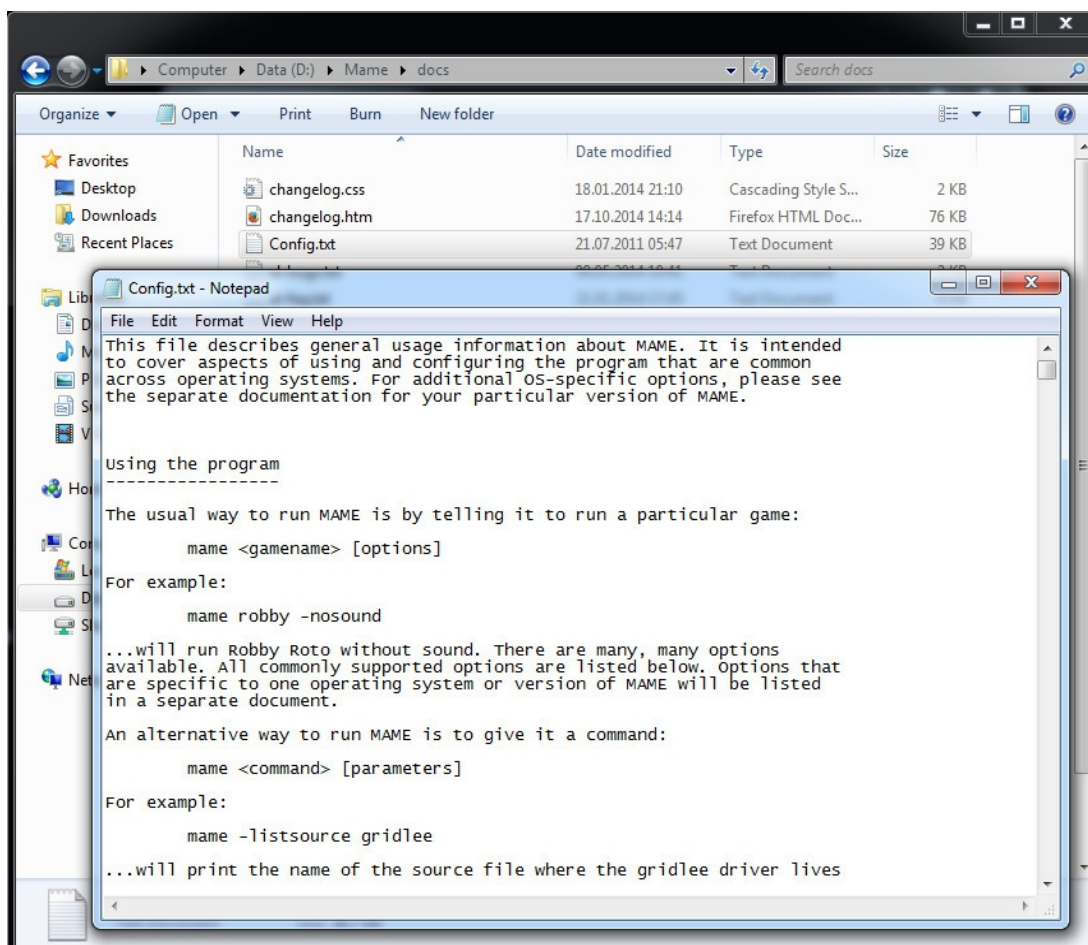

In each folder is a txt-file that describes the use of that folder. In the Cabinet folder for example you can store picture for cabinets. A lot of this folders are used within the MAMEui program for displaying the additional stuff (see next chapter).

Two files are included in MAME as a help. They are stored in the mame\docs folder and are named config.txt and windows.txt.

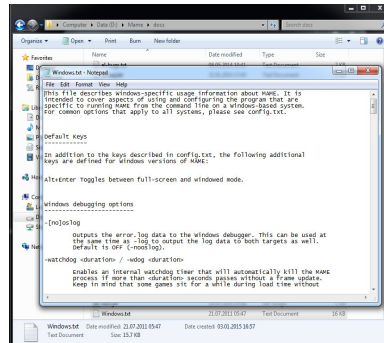

In the config.txt is described how you can use the command-line version of MAME. There are a lot of option that can be used to start a game. Please check this file yourself for more information I don't want to describe everything here again.

What is important to look at are the additional keys you can use within a game. For example “reset a game (F3)” or “take a snapshot (F12)”.

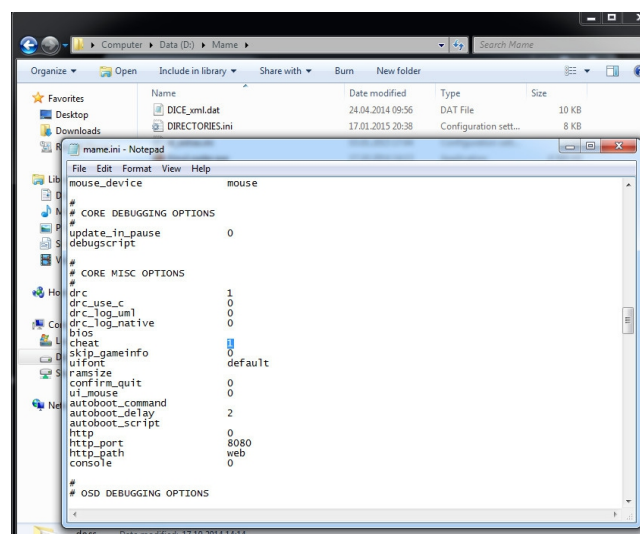

The other file is called “Windows.txt” and it contains additional information/possibilities for windows based computers.

Have you read everything? For sure not everything in details. There are so many options available and a lot of them you will never use. Don't worry about that but it is good to know where to look at when you need information.

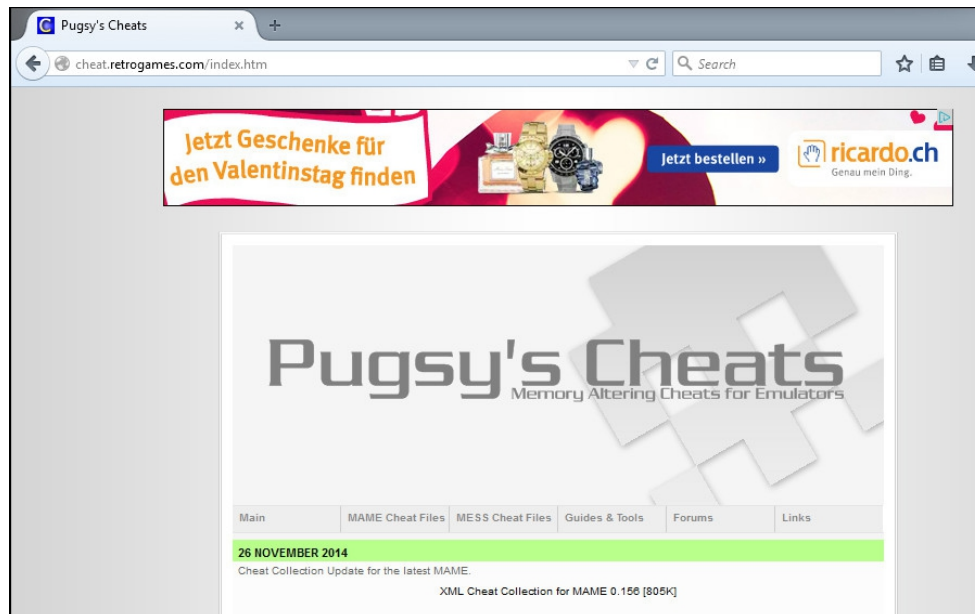

Let's show you now how you can enable the cheat mode within MAME. Sometimes maybe you want to play a round to the end without being all the time dead

Open the mame.ini file with notepad. Search for the option “Cheat” and change that value to “1”

Open a web-browser and navigate to “Pugsy's Cheats”

Download the cheat-file for MAME

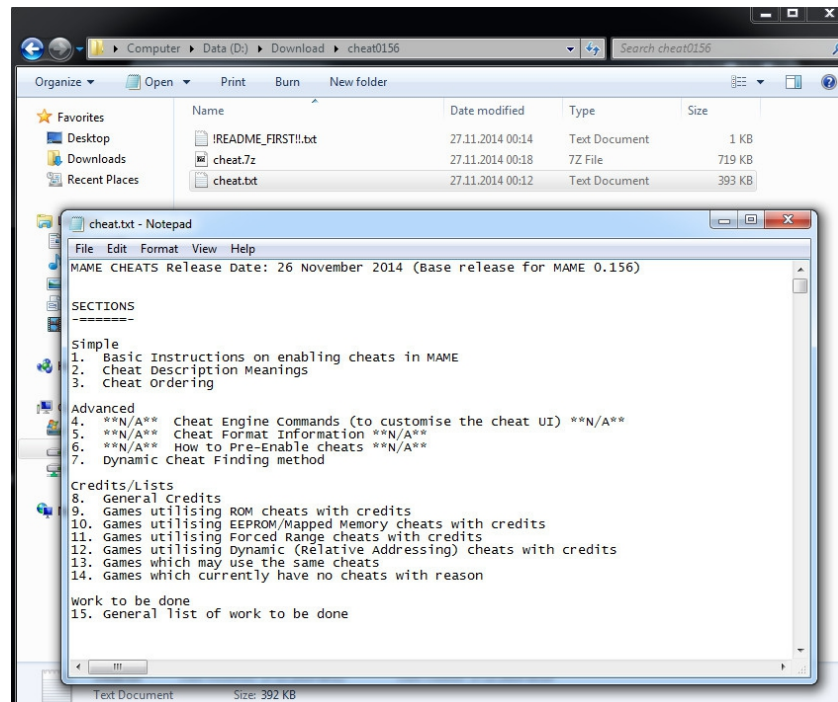

Extract the downloaded file to a separate folder

In this folder is a txt-file that describes everything.

Copy that cheat.7z file

...to the MAME folder.

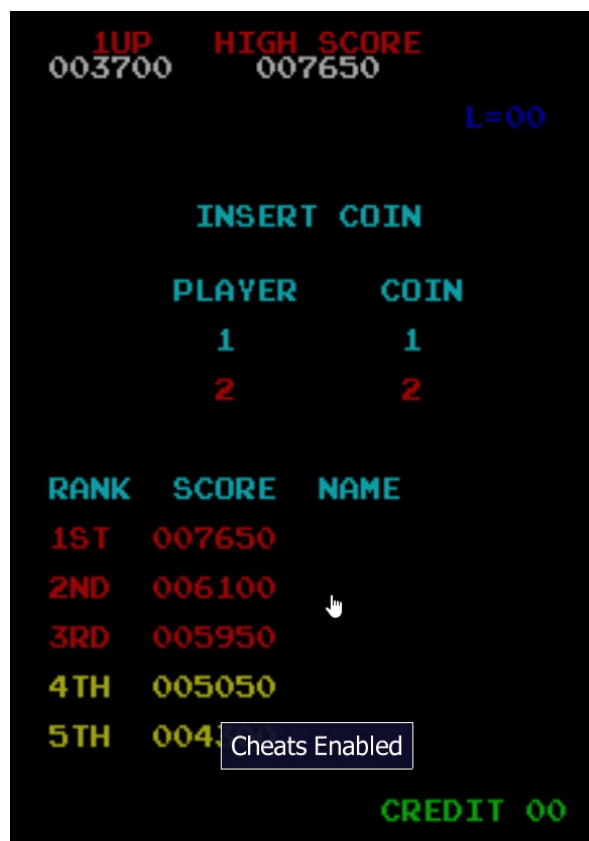

Why not in the “cheat” folder there is one? You could do it but you have to extract that cheat.7z first to this folder and there are a lot of cheat-files inside that file. It is better to have that file in a zipped format. It is also easier to replaced that with a newer version.

We are now ready for cheating. The cheat-option is enabled in our mame.ini and we have a cheat.7z as our database. Let's start again the game.

We can press “F6” for enabling or disabling the cheat-mode.

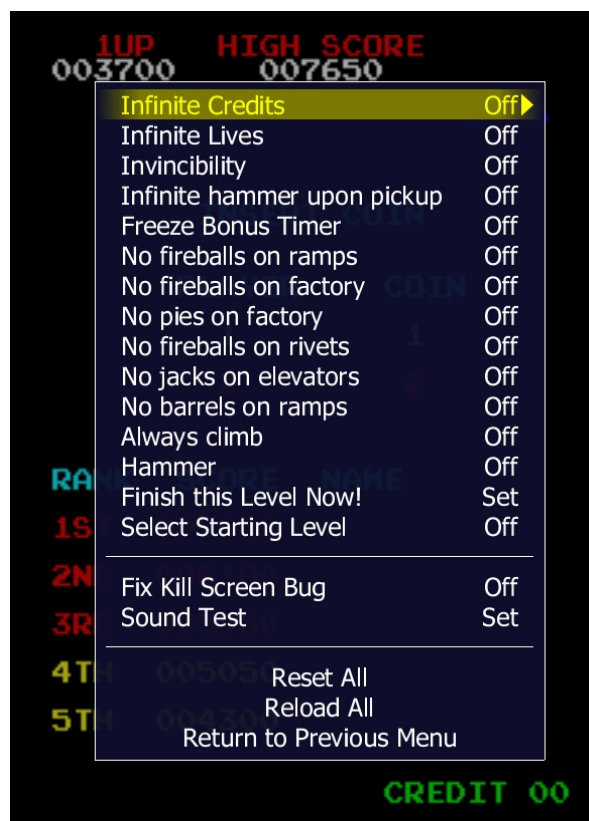

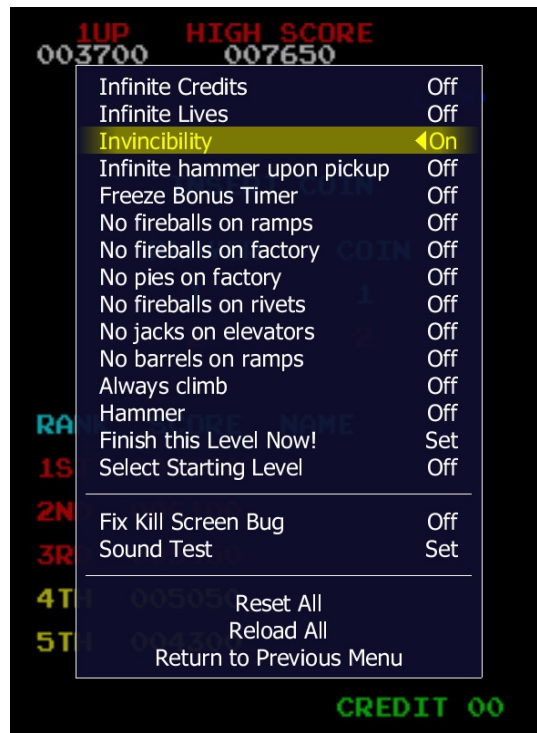

What you can cheat is inside the menu “cheat” available.

For Donkey Kong are a lot of possibilities available.

We enable for “testing” the entry “Invincibility”

Let's close that menu with “ESC” and start the game. And you will notice that Mario can go up the level without a jump.

With pressing “F6” again you can disable the “cheat-mode”.

There are for a lot of games cheats available but not for ever game. Visit the Pugsy web page and update your database (cheat.7z) with each MAME version.

I think that you have now enough information how you can play games with MAME. Keep in mind that you also in MAMEui or with a frontend must know how MAME operates. You must know how you can set your keys or what is available. Each game has settings or Dip options that maybe are not available in another game.

Visit http://wiki.mamedev.org/index.php?title=Frequently_Asked_Questions for more information and tips.

The command-line version is more used by advanced users or in combination with a front-end. Beginners should start with the MAMEui version, it is easier to handle ;-)

Installing MAMEui (Windows)

We have now installed our first emulator and can use it. But for a lot of people this command line program is not the first choice in usability. There are some MAME-Emulators around that has a graphical user interface (UI) but we use here the official windows MAMEui.

Open the following web-page on the web-browser

Scroll to the bottom and download the “MAMEui64”

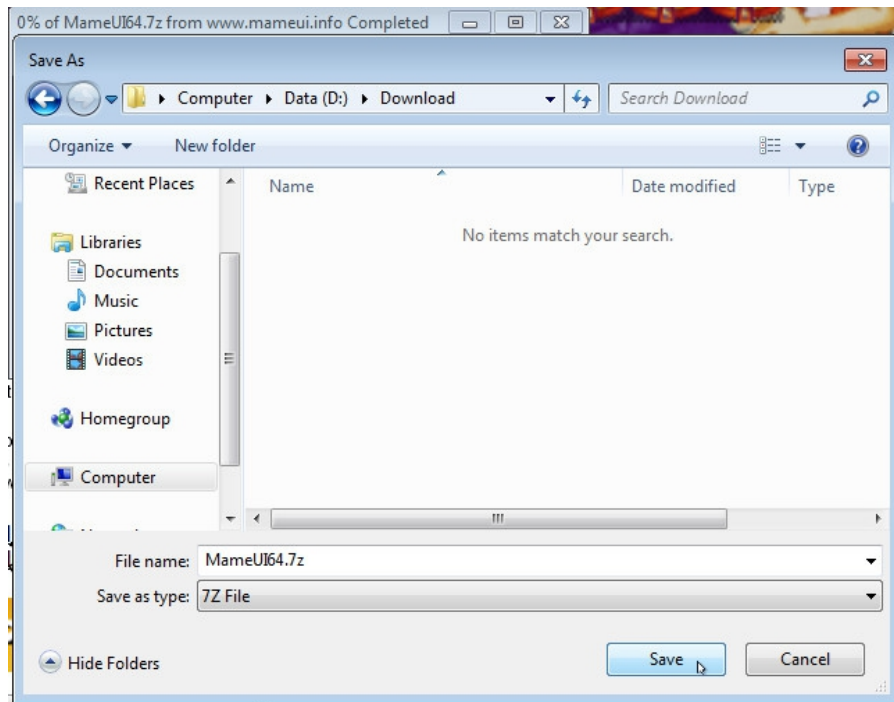

The 64-bit version is still compiled and released when there is no breakage with the core.

[IV/Play 1.5.5](#) • [MAMEUI64 .157](#) • [MAMEUI Source .157](#)
[Snapshots \(1\) \(2\) \(3\) & Update](#) • [Icons](#) • [CmAMEpro DAT Files](#) • [Forum](#) • [Benchmark](#)

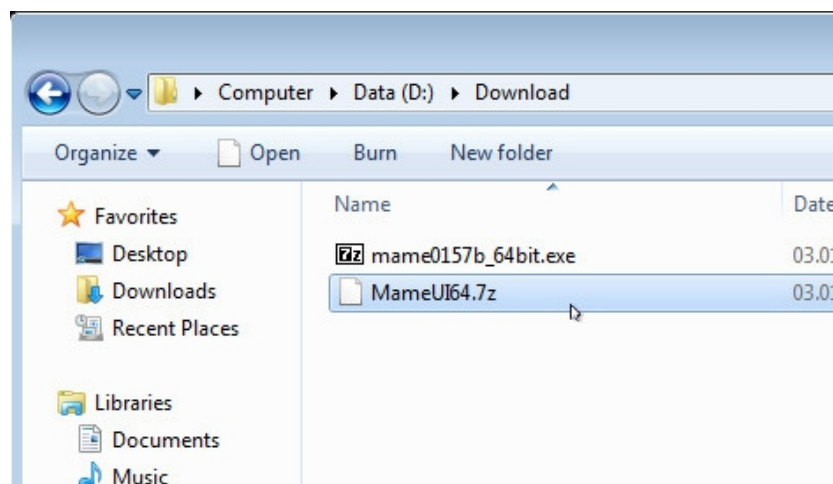

Powered by [Parcom.net](#)

Save it to our download folder

After downloading change to the download folder

The file is packed with 7-zip. We must first install 7zip on this machine to handle that file-type.

Download it from here (64-bit version)

7-Zip

7-Zip is a file archiver with a high compression ratio.

Download 7-Zip 9.20 (2010-11-18) for Windows:

Link	Type	Windows	Size
Download	.exe	32-bit x86	1 MB
Download	.msi	64-bit x64	1 MB

Download 7-Zip 9.37 beta (2015-01-03) for Windows:

Link	Type	Windows	Size
Download	.exe	32-bit x86	1 MB
Download	.msi	64-bit x64	1 MB

The download links above redirect you to download pages on SourceF

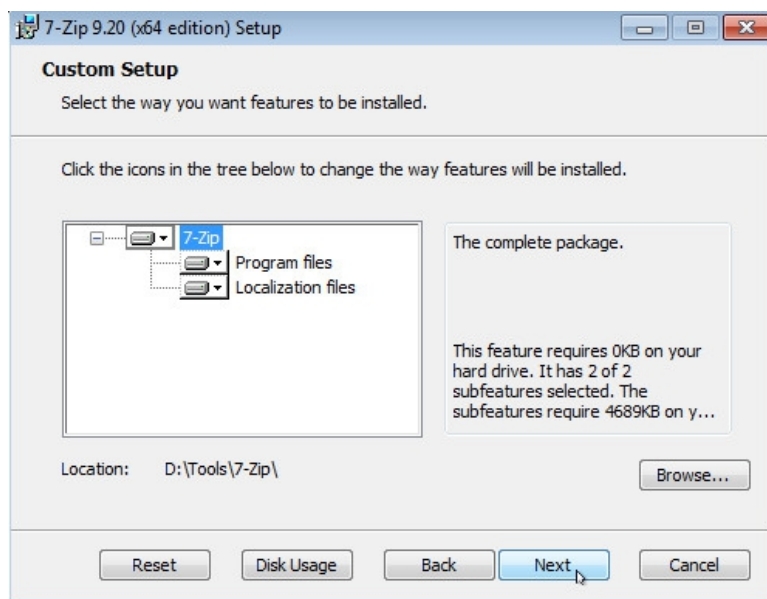

License

After downloading we must install the program

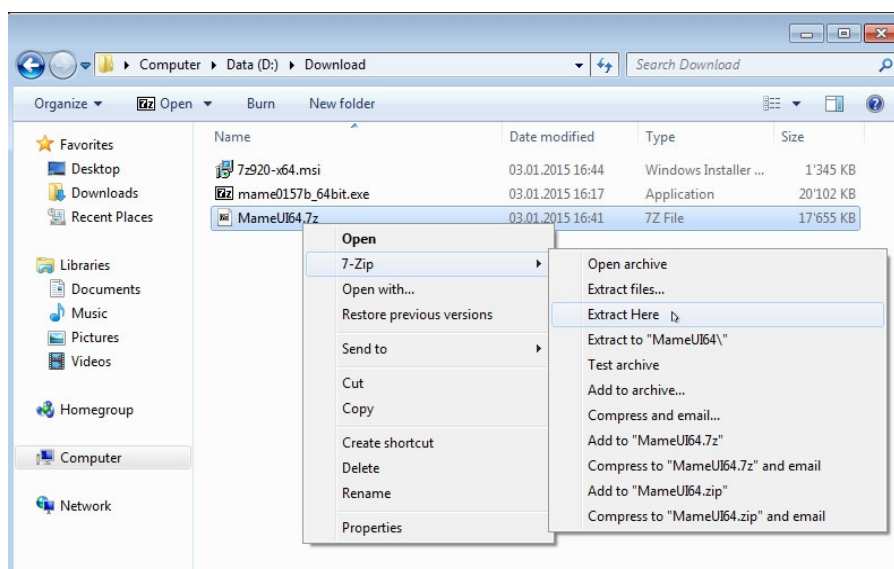

Start the installation and install it to the d:\tools\ folder

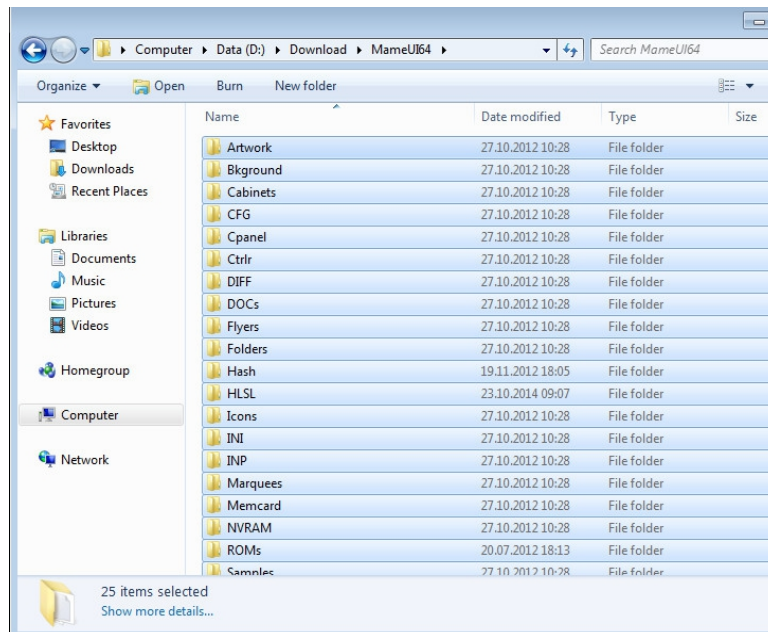

After 7-Zip is installed we can extract the downloaded MAMEUI64 file by pressing the right mouse button and choose “extract here”

! This archive-file has a folder name “MAMEUI64” inside the file. That's the reason we extract it not directly to the MAME folder.

Move the whole content from this folder

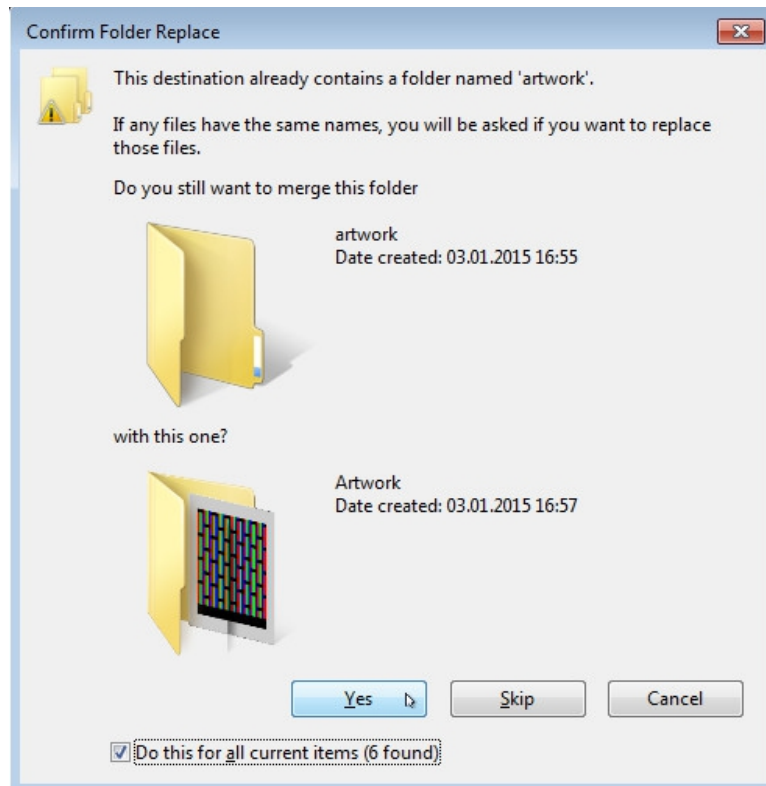

...to this place

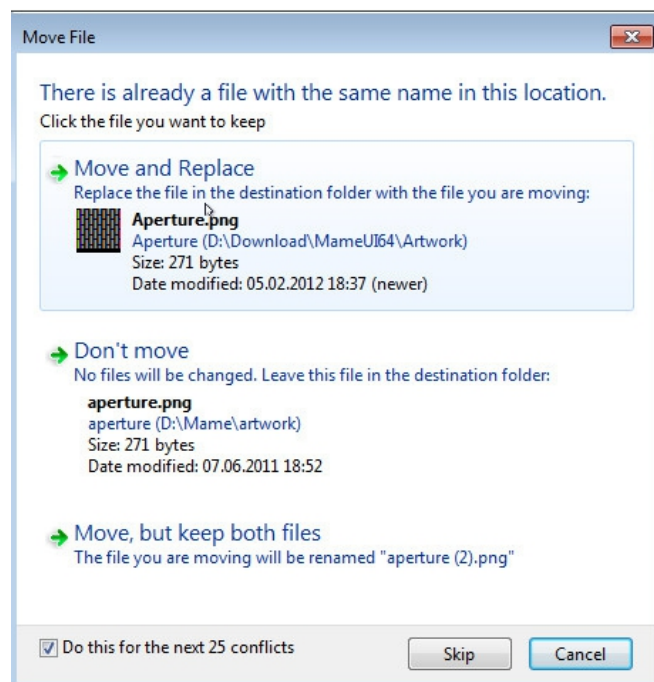

Overwrite the existing folders, say “yes” to the following folder question

Do the same for the files

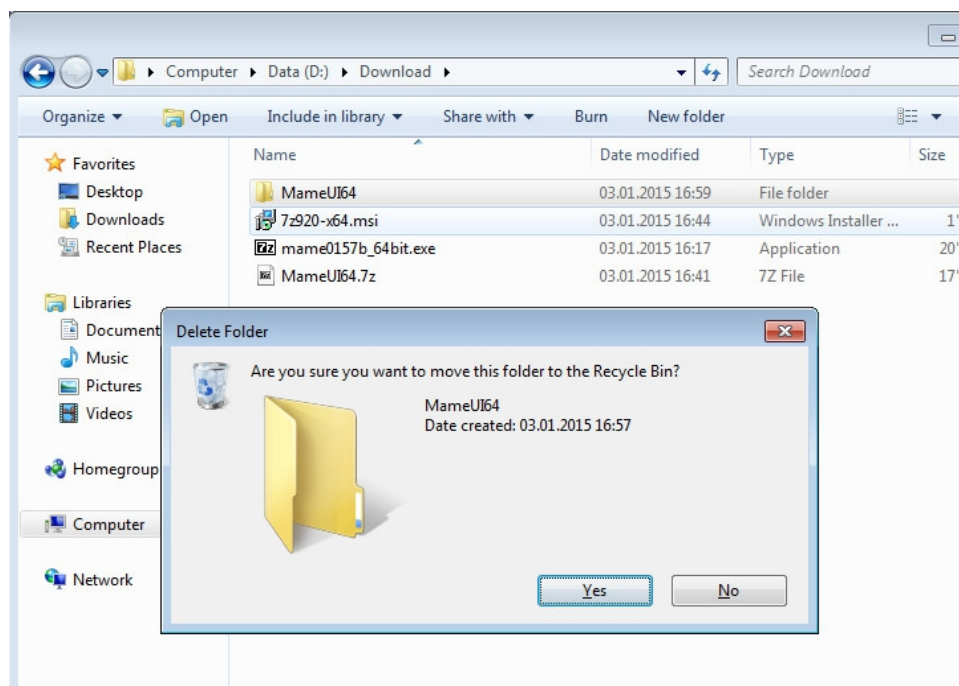

Your folder should look like that

Please remember that you delete the original folder in the download

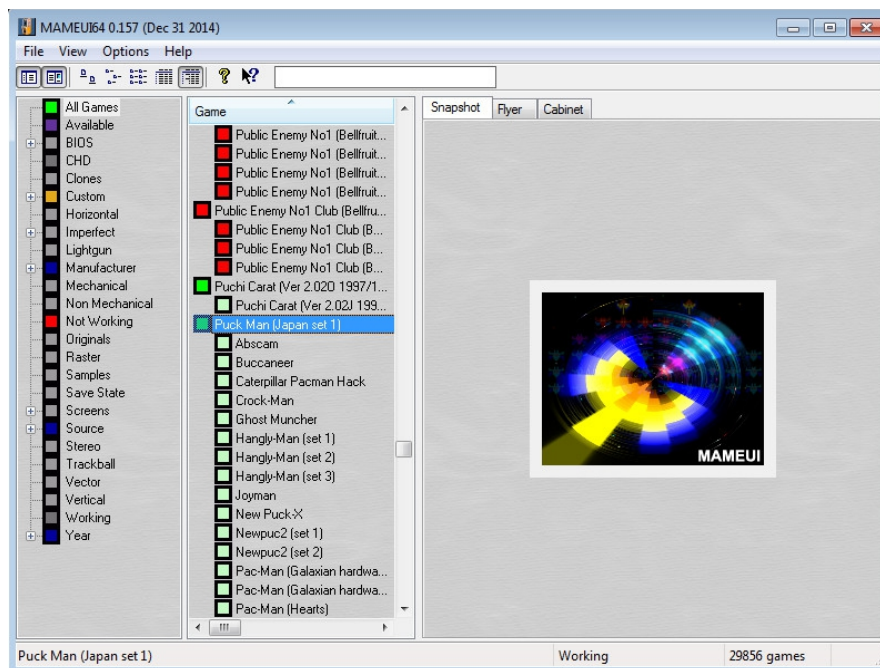

We start now the MAME with the MAMEui64.exe in the MAME folder

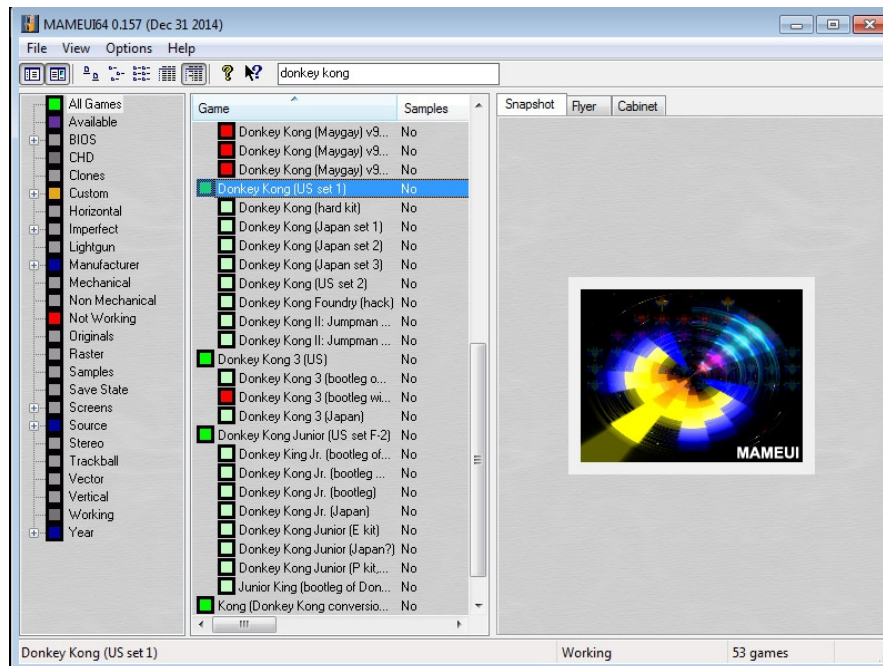

The program starts

Search for the “Donkey Kong” (dkong.zip is (US set1) version)

Double-clicking it and the game starts

Escape the emulator by pressing “ESC”

As this installation was not windows like we have no shortcuts on the desktop. Drag-and-drop the “mameui64.exe” by pressing the right mouse button to the desktop. In the appearing menu choose “create shortcuts here”

We have now a shortcut on the desktop.

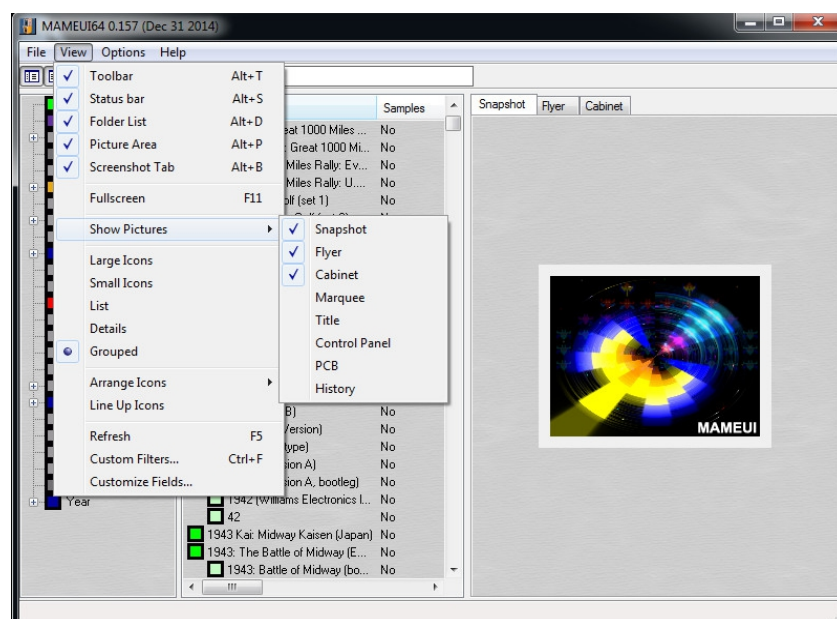

Installing add-ons for MAMEui

We have installed MAMEui and it looks ugly, isn't it?

Can we do things like displaying snapshots or do we have to create them ourself with “F12”? We can enable in the view more snapshots but how do we get them?

We enable all available options.

The answer is yes and I will show you where you can download additional stuff for MAMEui or using a Front-end.

! Yes you could also do it yourself within MAME. Start a game and press F12. It saves you a screen snapshot. But we are lazy and download them all.

Start a web-browser and navigate to the MAMEui home

IV/Play (pronounced 'Four Play') is a desktop oriented GUI front-end for MAME™. It was designed and commissioned by

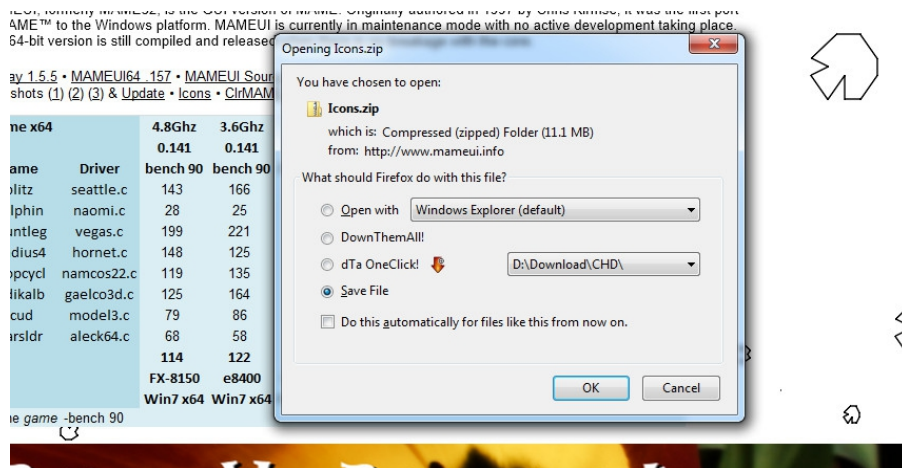

Scroll down and download the icons.zip that is available.

MAMEUI, formerly MAME32, is the GUI version of MAME. Originally authored in 1997 by C of MAME™ to the Windows platform. MAMEUI is currently in maintenance mode with no a The 64-bit version is still compiled and released when there is no breakage with the core.

[IV/Play 1.5.5](#) • [MAMEUI64_157](#) • [MAMEUI Source_157](#)
[Snapshots \(1\) \(2\) \(3\) & Update](#) • [Icons](#) • [CirMAMEpro DAT Files](#) • [Forum](#)

Mame x64		4.8Ghz	3.6Ghz	3.7Ghz	4.28Ghz	4.5Ghz	4.8Ghz
		0.141	0.141	0.141	0.141	0.141	0.141
Game	Driver	bench 90	bench 90	bench 90	bench 90	bench 90	bench 90

Save it to the download folder.

And move it afterwards to the mame\icons folder.

Now look at the MAMEui → it has changed and displays entries with little icons :-)

We want now to download snapshots. AntoPISA is providing them all for a long time and updates them when a new MAME version appears (Great Work AntoPISA).

We open a web-browser and navigate to the Progetto-Snaps homepage.

We choose “Snapshots” from the left menu

We are now in the Snapshots section

We are looking for the snapshots. Normally it is describe as InGame snapshots so we choose to download the hole-package (as we have nothing in our MAME environment). Click it ...

..and it brings you to a filehoster. Click “download” and save it to the download folder.

! Keep in mind that this addon-packages can be very big in size.

Open the download folder and move the file

... to the mame\snapshots folder

We must rename this zip-file that it should named like the folder name

Now switch over to MAMEui and check if the snapshots are visible ..

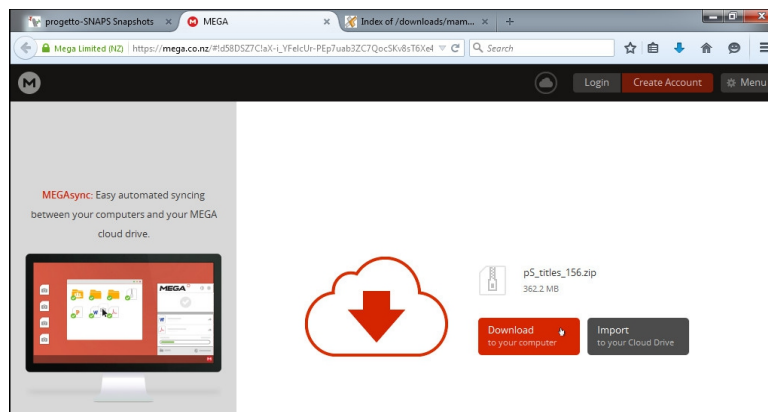

Great stuff AntoPISA thanks for that :-)

We are doing now another category named “Titles”. Use the web-browser again and download the hole-package from the site.

And save it to the download folder.

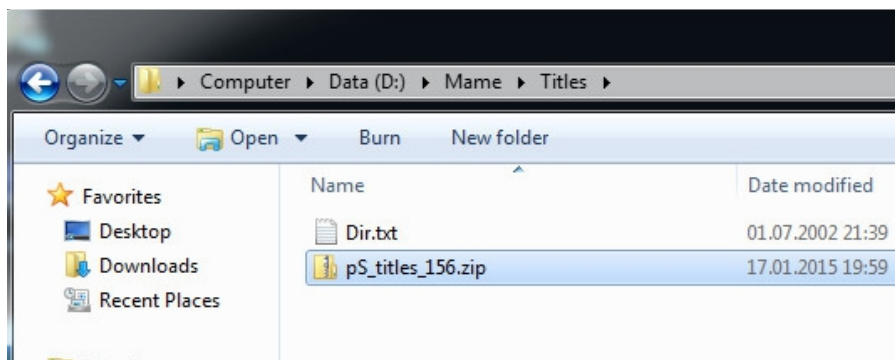

We do the same for this zip file: move it ...

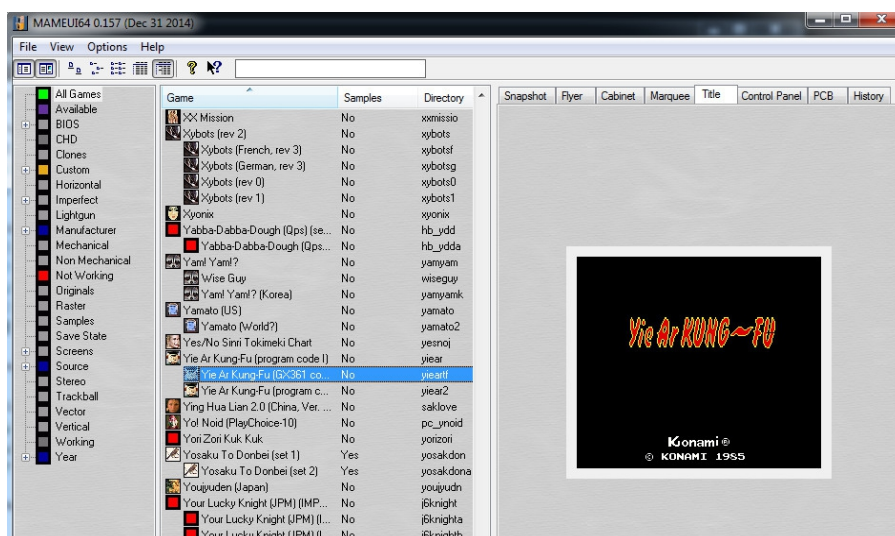

..to the mame\Titles folder.

And rename it to “titles.zip” (same as the folder name).

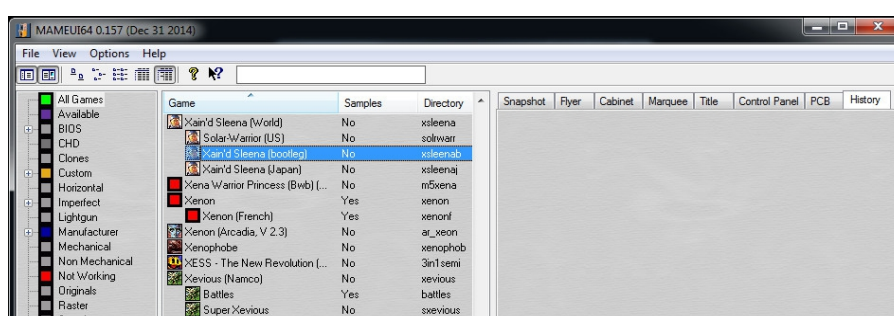

Look in MAMEui under “Title” → you can see now the picture.

We have now Ingame and Titles done. Do that with all the other available add-on you want. Please note that not all of them have the complete set for downloading. I have made an example in the CLRMAME section how to download all parts and rebuilds it to one packages. But that needs knowledge of a ROM-Manager and how-to-use-it.

There is also an item called “History”, what's that ?

Let's solve this item first and we do get an answer for “what is that for”.

Open a web-browser and navigate to ...

Download the 7z-file to the download folder.

History.dat 1.57 for MAME and MESS 0.157 now available! It contains information

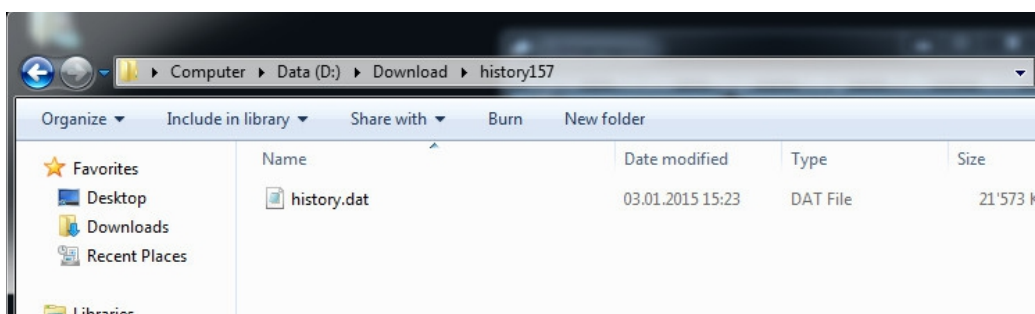

[Download History.dat 1.57 \(zip file\)](#)

[Download History.dat 1.57 \(7z file\)](#)

We extract the downloaded file to a folder called “history157”.

Move the extracted file from the folder “history157”

.. to the mame folder.

Now we are looking in MAMEui what is the value from this file.

It displays now information about the game, nice thing.

There are a lot of more files /add-on available in the web. If you are into MAME and have spend some more time you will get the information sooner or later.....

Using MAMEui

Start MAMEui

As you may have seen in the “config.txt” in the Mame\docs folder the command-line version of MAME has a lot of option to start a game with a special configuration. With MAMEui you can do this easily within the User Interface (Ui).

Under view is everything to configure how MAMEui is presented to you. Play around with all the available options.

In the “options sections is everything for the emulator itself.

Go to “Options - Default Game Options”. We are looking at some settings there. Under “Controllers” you can set a special layout when you have for example a X-Arcade controller (<http://shop.xgaming.com/>) or set the joystick the right way there.

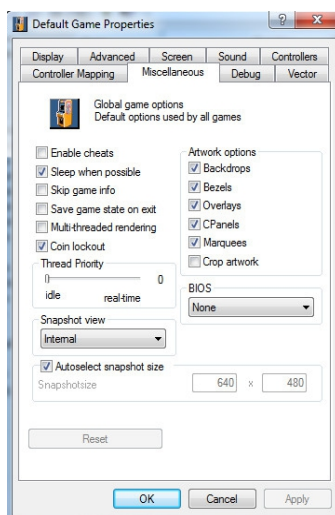

If you have additional devices you should enable that under “Controller Mapping”

Under “Miscellaneous” are for example the “enable cheats” or the artwork options.

Artworks are add-on that you can use for MAME. You must download them from Mr.Do website. There is also a good FAQ that explain everything about Artworks. Download them to your mame\artwork folder and enable it in this setting. Bezels contains additional graphics or instructions of a game.

http://mrdo.mameworld.info/mame_artwork_faq.php

Here is an example for playing Pac-Man with the “Bezels” enabled.

Under “Options - Directories” you can change the default path for everything is available. For example when you have your ROMs and CHDs not in the same folder you can add the CHD-Folder as a second path under “ROMs”. All the settings are default that means when you have all your ROMS in the MAMUI folder “ROMs” you must change nothing. Let's look at the picture for showing you.

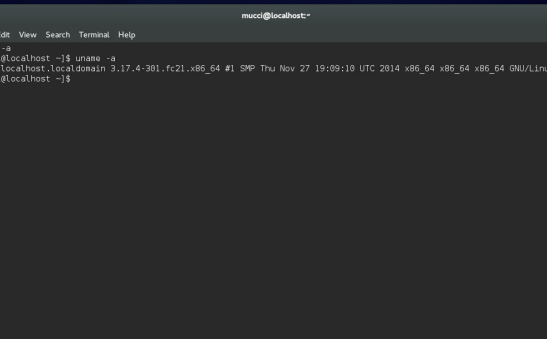

That was it for the MAMEui. Keep in mind that when you have started a game you need to know how to handle the emulator itself as discussed in the MAME section.

I have only limited Linux knowledge but I have installed successfully MAME on Fedora 21. I hope you will get enough information to install MAME on your distro.

The screenshot shows a terminal window titled "Terminal" with a dark background. The prompt is "mucci@localhost:". The command "uname -a" has been entered and executed. The output is displayed on the next line: "Linux localhost.localdomain 3.17.4-301.fc21.x86_64 #1 SMP Thu Nov 27 19:09:10 UTC 2014 x86_64 x86_64 x86_64 GNU/Linux".

Official Source Code Packages

The latest official MAME and MESS release is version 0.158. The table below provides links to the source code.

The table below provides links to the official source packages. Larger files are hosted on external mirrors, selected at random, which may require a temporary redirect to the mirror site in order to download the file.

File	Size	Description	Downloads
whatsnew_0158.txt	9 KB	List of what is new in this MAME release	
messnew_0158.txt	4 KB	List of what is new in this MESS release	
mame0158s.exe	32826 KB	MAME and MESS 0.158 sources in self-extracting 7zip format (Windows only)	219
mame0158s.zip	45523 KB	MAME and MESS 0.158 sources in ZIP format (all platforms)	301

Thanks to our mirrors: [MAMEWorld](#) • [EmuMovies](#)

Make a folder “MAME” and extract the downloaded file. You have to do it twice (double packed). Be sure that you extract the mame.zip file into the created folder MAME.

```
mucci@localhost:~/Downloads

File Edit View Search Terminal Help
[mucci@localhost Downloads]$ ls
mame0158s.zip
[mucci@localhost Downloads]$ unzip mame0158s.zip
Archive: mame0158s.zip
  inflating: mame.zip
[mucci@localhost Downloads]$ mkdir MAME
[mucci@localhost Downloads]$ unzip mame.zip -d MAME
```

Everything is now ready for compiling. Change to the MAME folder and execute “make”.

```

[mucci@localhost MAME]$ ./mame64 -?
M.A.M.E. v0.158 (Jan 29 2015) - Multiple Arcade Machine Emulator
Copyright Nicola Salmoria and the MAME team

MAME is an emulator: it reproduces, more or less faithfully, the behaviour of
several arcade machines. But hardware is useless without software, so an image
of the ROMs which run on that hardware is required. Such ROMs, like any other
commercial software, are copyrighted material and it is therefore illegal to
use them if you don't own the original arcade machine. Needless to say, ROMs
are not distributed together with MAME. Distribution of MAME together with ROM
images is a violation of copyright law and should be promptly reported to the
authors so that appropriate legal action can be taken.

Usage: MAME [game] [options]

    MAME -showusage      for a brief list of options
    MAME -showconfig     for a list of configuration options
    MAME -listmedia      for a full list of supported media
    MAME -createconfig    to create a mame.ini

For usage instructions, please consult the files config.txt and windows.txt.
[mucci@localhost MAME]$
```

Using MAME (Linux)

Using MAME under Linux is the same as using it under Windows. First create the `mame.ini` config-file.

```

```

And yes it works :-)

I know that we have installed MAME not in a perfect way. But I'm sure that you as a Linux expert will do it much better and have seen how we can install/use MAME in a Linux environment :-)

Chapter 3: MESS

In this chapter we look into MESS (Multi Emulator Super System) how to install and using it. As it shares the same source-code you can create from the MAME-Source-code also the MESS binaries. You will see that the handling is similar to MAME.

Installing MESS (Windows)

First we create a folder called “Mess” on the data drive

From the MAMEdev website we download the packages

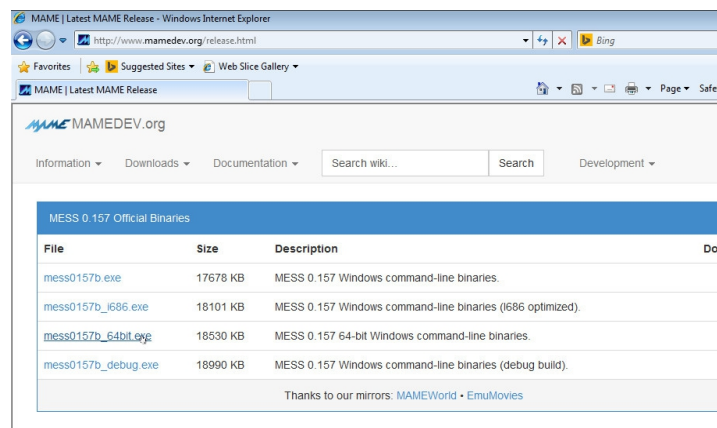

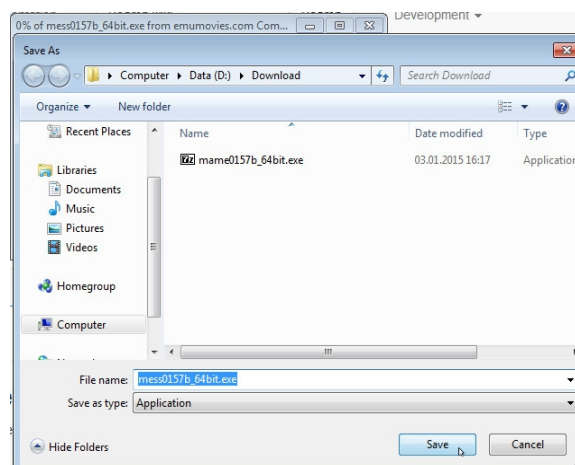

Under “Latest Release” you will find the download

Scroll down to the MESS-Section and choose the 64bit version to download

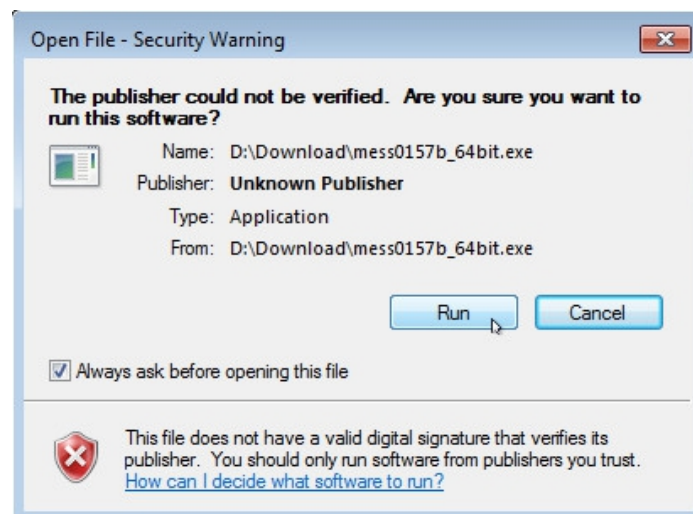

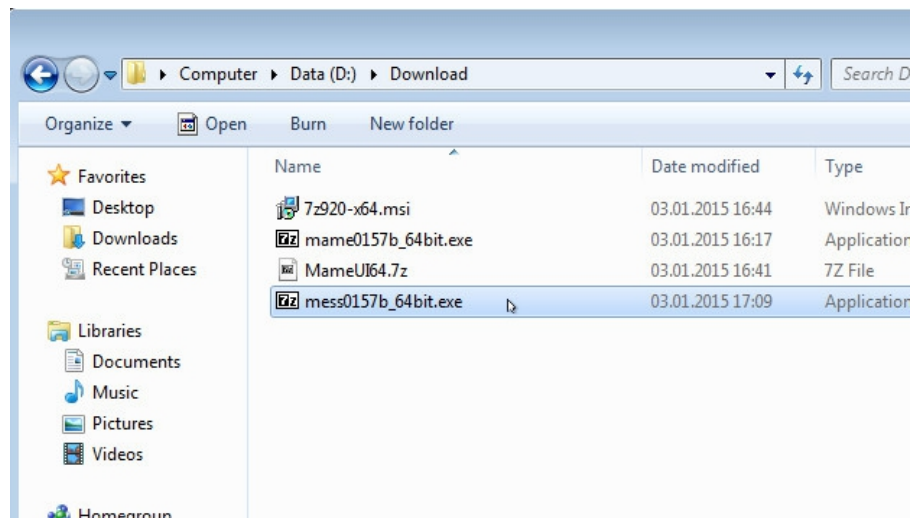

Save it to our download folder

Start the installation by double-clicking the exe

Extract it to the mess folder

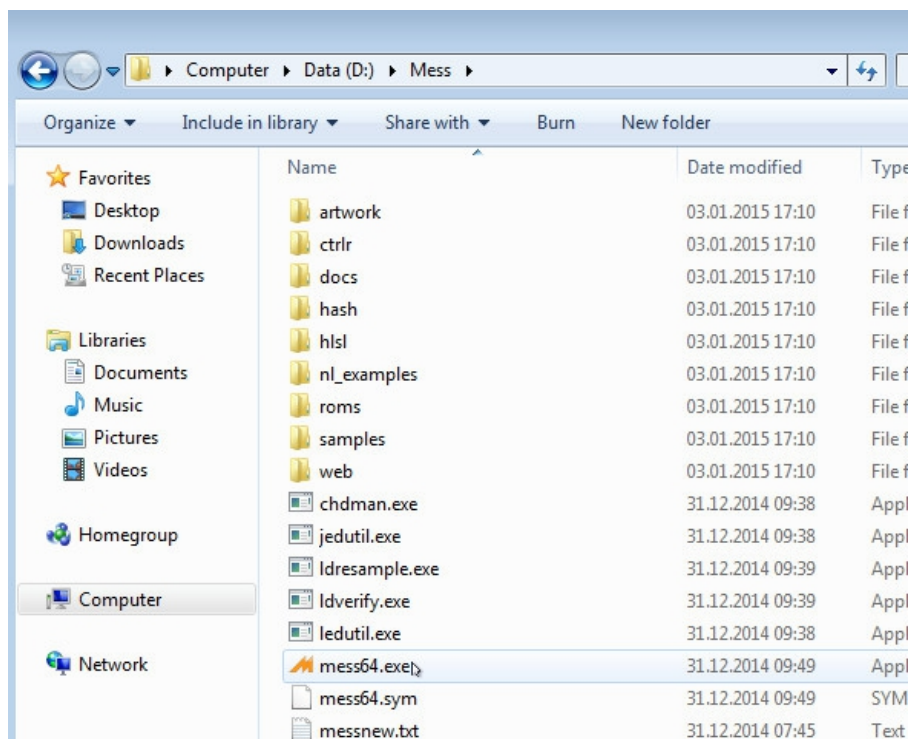

Your MESS folder should look like that

Start the emulator mess64.exe

No systems found. Please check the rompath specified in the mess.ini file.

If this is your first time using MESS, please see the config.txt file in the docs directory for information on configuring MESS.

Exit

The screenshot shows a Windows 7 desktop environment. A File Explorer window is open, displaying the contents of the 'Mess' folder located at 'Data (D:)'. The folder contains several subfolders: 'artwork', 'cfg', 'ctrl', 'docs', 'hash', and 'hld'. The 'hld' folder is currently selected. Below the File Explorer, a Command Prompt window is open, showing the following text:

```
C:\Windows\system32\cmd.exe
Microsoft Windows [Version 6.1.7601]
Copyright (c) 2009 Microsoft Corporation. All rights reserved.

C:\Users\NAME>cd d:\Mess
C:\Users\NAME>dir
d:\Mess>mess64.exe -?
```

The Command Prompt window also shows the file path 'C:\Windows\system32\cmd.exe' at the top. The desktop background is a solid blue color.

We create a default mess.ini for this emulator by typing “mess64.exe -createconfig” (yeah right exactly as we did it for MAME)

The screenshot shows a Windows file explorer window with the following files and folders:

- aries
- ocuments
- Music
- ictures
- ideos
- megroup
- omputer
- twork
- hash
- hsl
- nl_examples
- roms
- samples
- web
- chdman.exe
- jedutil.exe
- ldresample.
- ldverify.exe
- ledutil.exe
- mess.ini
- mess64.exe
- mess64.sym
- messnew.txt
- nltool.exe
- romcmp.exe
- unidasm.exe
- whatsnew.txt

A command prompt window is open, showing the following text:

```
C:\Windows\system32\cmd.exe
MESS is based on MAME Source code
Copyright Nicola Salmoria and the MAME team

MESS is an emulator: it reproduces, more or less faithfully, the behavior
several computer and console systems. But hardware is useless without so
so a file dump of the ROM, cartridges, discs, and cassettes which run on
hardware is required. Such files, like any other commercial software, are
copyrighted material and it is therefore illegal to use them if you don't
the original media from which the files are derived. Needless to say, th
files are not distributed together with MESS. Distribution of MESS toget
with these files is a violation of copyright law and should be promptly
reported to the authors so that appropriate legal action can be taken.

Usage: MESS [system] [media] [software] [options]

MESS -showusage for a brief list of options
MESS -showconfig for a list of configuration options
MESS -listmedia for a full list of supported media
MESS -createconfig to create a mess.ini

For usage instructions, please consult the files config.txt and windows.
d:\Mess>mess64.exe -createconfig
d:\Mess>
```

This ini-file contains the settings. Leave it as it is for now.

The screenshot shows a Notepad window titled "mess.ini - Notepad" with the following content:

```
# CORE CONFIGURATION OPTIONS
#
readconfig      1
writeconfig     0

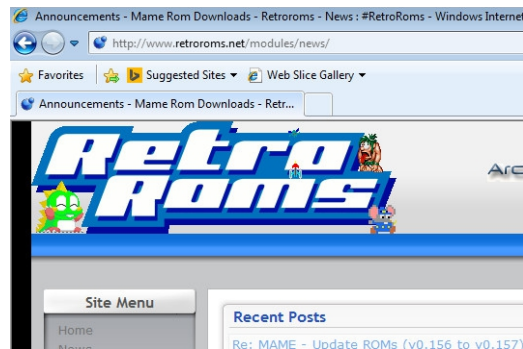

# CORE SEARCH PATH OPTIONS
#
rompath         roms
hashpath        hash
samplepath      samples
artpath         artwork
ctrlrpath       ctrlr
inipath         .;ini
fontpath        cheat
cheatpath       cheat
crosshairpath   crosshair

# CORE OUTPUT DIRECTORY OPTIONS
#
cfg_directory   cfg
nvram_directory nvram
input_directory inp
state_directory sta
snapshot_directory snap
diff_directory  diff
comment_directory comments

# CORE STATE/PLAYBACK OPTIONS
#
state
```

Now after the installation we want to test it. Again go to Retroroms.net

Under “Download”

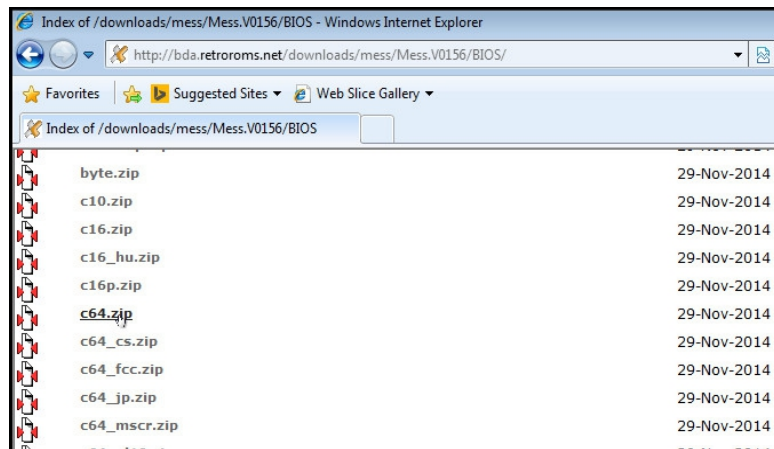

Switch to the Mess-Section

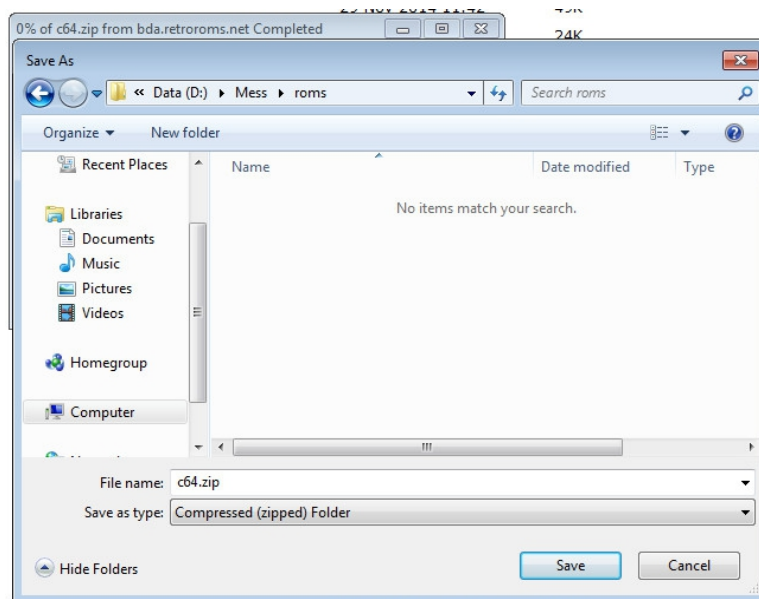

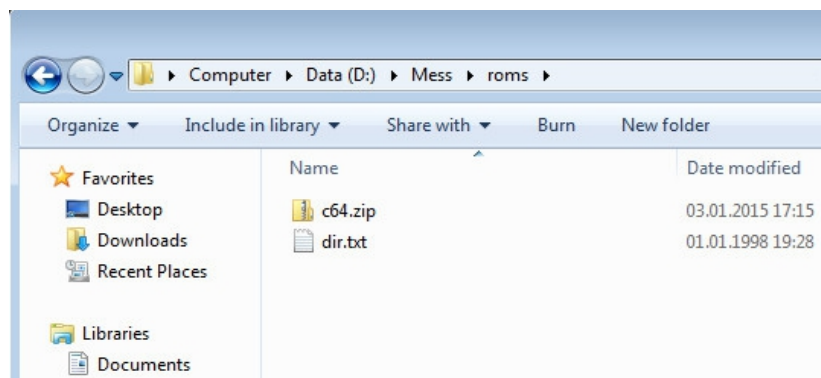

And download the BIOS for the c-64

Download it to the Mess/roms folder

And as we did it for MAME leave the zip-file untouched..

We try now to start the emulator with the C-64 BIOS

Upps seems that we have a missing file → c1541

Download from Retroroms.net this c1541.zip

And place it to the MESS/ROMs folder..

Now we start the same command again

```
d:\Mess>mess64.exe c64.zip -rompath d:\Mess\roms\
```

Yes the emulator starts. The following message must be confirmed by pressing “o” and “k” → be sure that you own that system!

Now it displays the hardware specification that the C-64 have.

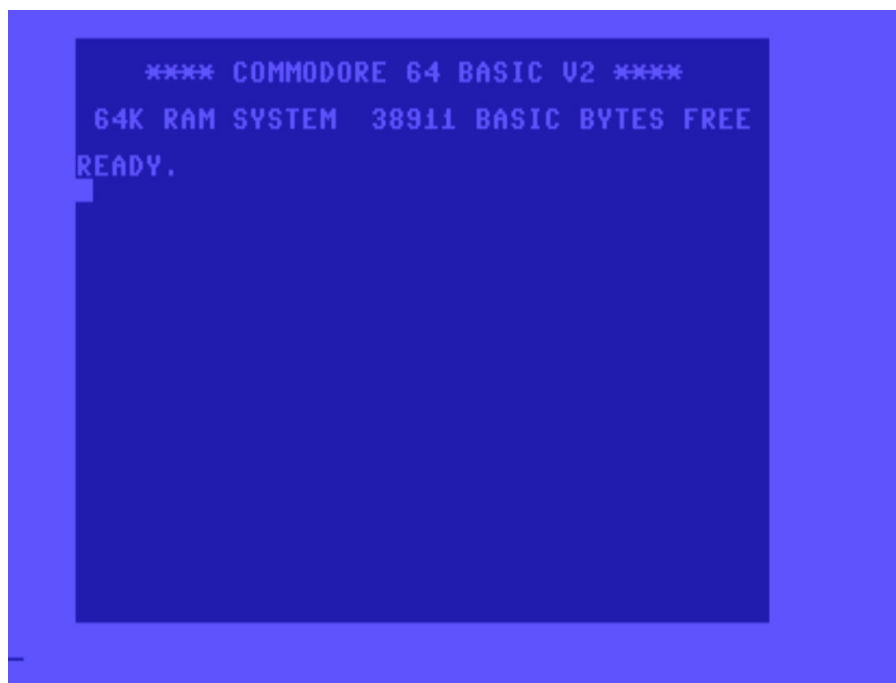

```
Commodore 64 (NTSC)
1982 Commodore Business Machines
Driver: c64.c

CPU:
M6510 1.022727 MHz
MOS6567 1.022727 MHz
2×MOS6526 1.022727 MHz
M6502 1.000000 MHz

Sound:
Speaker
MOS6581 1.022727 MHz

Video:
418 × 235 (H) 59.826087 Hz
```

The Emulator starts the C-64 emulation

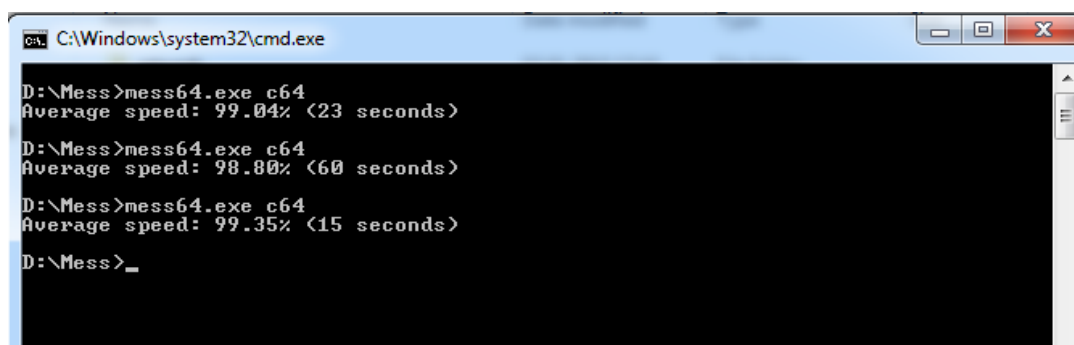

When you want to quit the emulator you will see that “ESC” does not work. But how can we exit it? Press the key “Scroll lock” and you will see a pop-up that tells you that the keyboard emulation status is changed.

And now you can quit the emulator by pressing the “ESC”

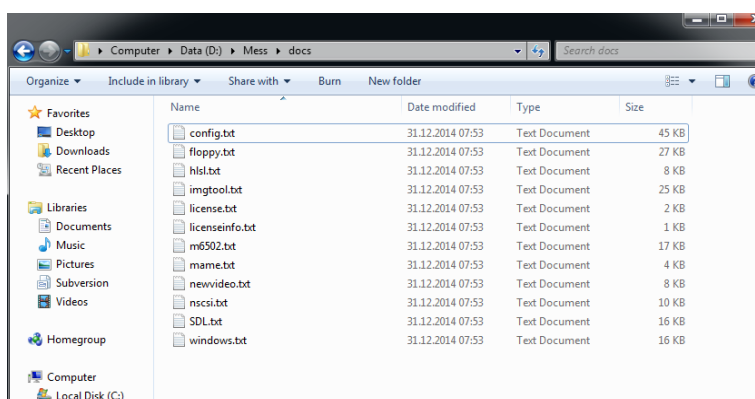

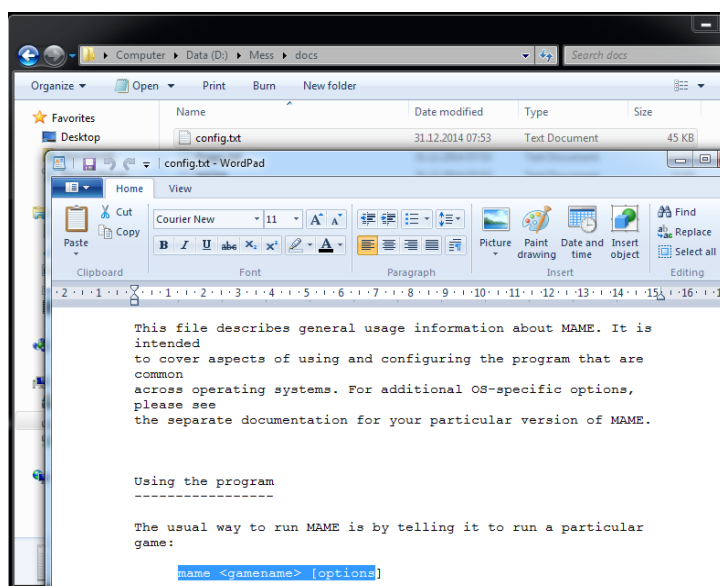

Using MESS (Windows)

We have installed MESS and started to emulate a C-64, that was quite easy. Mess is a little bit complicated than MAME. You have to load first the system you want to use and after that you have to choose from which media a game should be loaded. Sounds not easy, let's try it step by step.

Hmm MAME had some txt-file in the doc folders as a help. Maybe MESS has that too

What's that? MAME?

Yeah a little disappointed only MAME information is available. But no worry we will create a txt-file with MESS information ourself.

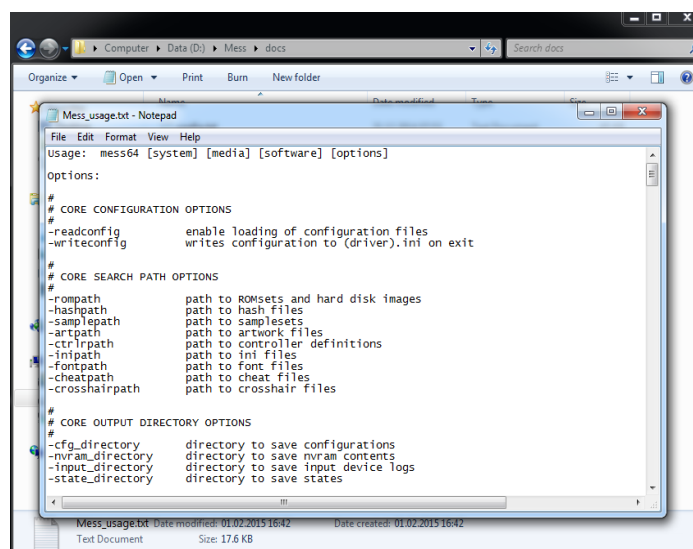

We use the emulator itself to write some information to a text file.

We have now an information text file.

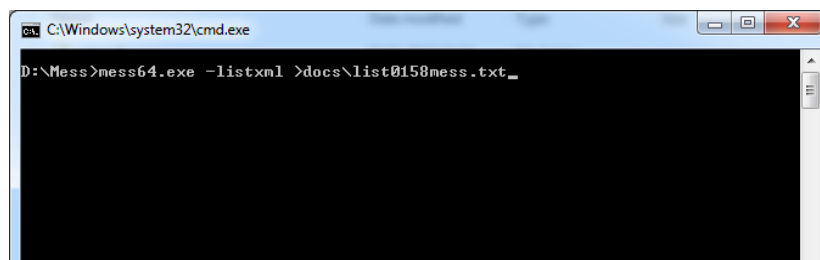

In this text file are all available options listed.

Okay so good so far but this command “mess.exe <system> <media> <software> <options>” gives us more questions than answer.

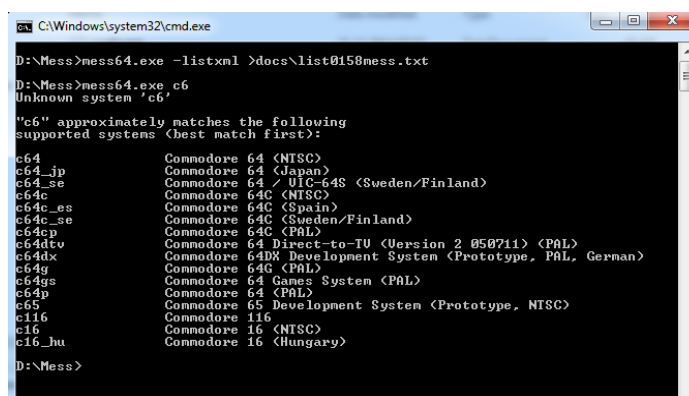

How do I know what system is available? Let's dump the emulated software into a file (also known as a DAT-file).

When we open that file in Notepad we can find systems but it is not a perfect way to find out if a system is supported or not.

But is there not an easy way to find out what we are looking for? Yes it is and it is so simply, just type in “mess64.exe” and followed by some letters. If the emulator can not find this entry it will displays systems that could be used instead. Okay let's display now what c64 systems are available ...

```
D:\Mess>mess64.exe -listxml >docs\list0158mess.txt
D:\Mess>mess64.exe c6
Unknown system 'c6'

"c6" approximately matches the following
supported systems (best match first):

c64      Commodore 64 (NTSC)
c64_jp   Commodore 64 (Japan)
c64_se   Commodore 64 / VIC-64S (Sweden/Finland)
c64c     Commodore 64C (NTSC)
c64c_es  Commodore 64C (Spain)
c64c_se  Commodore 64C (Sweden/Finland)
c64cp    Commodore 64C (PAL)
c64dte   Commodore 64 Direct-to-TU (Version 2 050711) (PAL)
c64dx    Commodore 64DX Development System (Prototype, PAL, German)
c64g     Commodore 64G (PAL)
c64gs    Commodore 64 Games System (PAL)
c64p     Commodore 64 (PAL)
c65      Commodore 65 Development System (Prototype, NTSC)
c116     Commodore 116
c16      Commodore 16 (NTSC)
c16_hu   Commodore 16 (Hungary)
```

One step done we know now what system we can use. We will pick up the c64 as our example. And what was the next question, ah yes what “media” you want to use. This can be different for each system. You can find it out by typing this command:

```
D:\Mess>mess64.exe c64 -listmedia
SYSTEM      MEDIA NAME <brief>      IMAGE FILE EXTENSIONS SUPPORTED
-----
c64         cassette    <cass>      .wav .tap
           floppydisk  <flop>     .d64 .g64 .g41 .d77 .d88 .1dd .dfi .i
md .ipf .mfi .mfm .td0 .cgm .cqi .dsk .a0 .e0 .crt
           cartridge  <cart>     .80 .a0 .e0 .crt
           quickload  <quik>     .p00 .prg .t64

D:\Mess>
```

That makes sense. Okay we know now what media we want to load, but how do I know what game could be loaded? There is an option called “softwarelist” that could helps us. Let's dump that information into a file.

```
C:\Windows\system32\cmd.exe
D:\Mess>mess64.exe c64 -listsoftware >docs\c64-softwarelist.txt
```

In this generated txt-file you will find the games which are supported and with what media.

```
c64-softwarelist.txt - Notepad
File Edit Format View Help
</part>
</software>
<software name="zaxxon">
  <description>Zaxxon</description>

D:\Mess>mess64.exe c64 -cart zaxxon
zaxxon <1984><synapse>.80 NOT FOUND <tried in c64 c64_cart\zaxxon zaxxon>
zaxxon <1984><synapse>.a0 NOT FOUND <tried in c64 c64_cart\zaxxon zaxxon>
FATALERROR: Required files are missing, the system cannot be run.
D:\Mess>_
```

We download the zaxxon from the internet and put it into a folder called “c64_cart” in the mess\roms folder. Why? See the pic above it search for this game in c64_cart\zaxxon. And the ROMs folder is already in the mess.ini defined.

Start the command again

```
C:\Windows\system32\cmd.exe

D:\Mess>mess64.exe c64 -listsoftware >docs\c64-softwarelist.txt

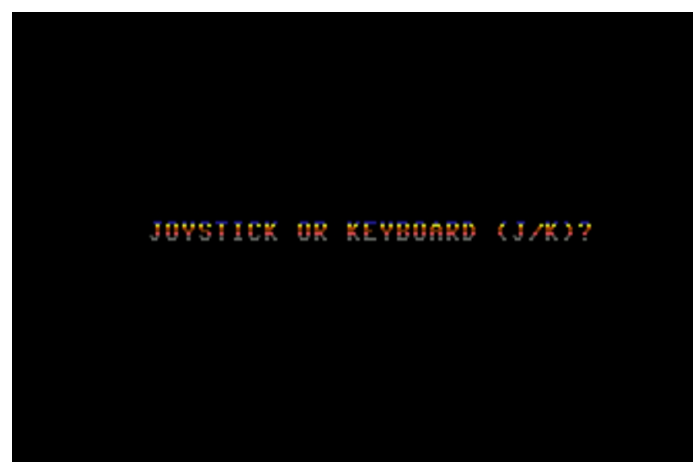

D:\Mess>mess64.exe c64 -cart zaxxon
zaxxon <1984><synapse>.80 NOT FOUND (tried in c64 c64_cart\zaxxon zaxxon)
zaxxon <1984><synapse>.a0 NOT FOUND (tried in c64 c64_cart\zaxxon zaxxon)
FATALERROR: Required files are missing, the system cannot be run.

D:\Mess>mess64.exe c64 -cart zaxxon
```

The emulator starts ...

..and the wanted game too

The operating is the same as it is in MAME so I will not describe it here again.

When we want to pause the game with “p” remember that this is a command that the system does not know. You have to press the “scroll lock” key first to have the option “p” available. It is a little tricky to change that keyboard mode. Now we are ready to fly with “zaxxon” ...

The software could also be stored outside the ROM-folder for a better organisation. Let's say we want the software here:

Move the c64_cart folder to this location.

Start zaxxon again with the last commando and yes it will fails.

There are now two options to start it again. First is that you describe in your command where the carts and ROMs are:

The second option is that you write that into your mess.ini under [ROMpath]

Start the game again and you will see that it does now work with a separate software folder.

The structure within this software folder e.g. “c64_cart” is hard-coded in MESS. You can't change that the emulator search for the c64 carts below in a folder called c64_cart.

We have now seen how does MESS operates. Let's see if the MESSui is not a better way for playing a game

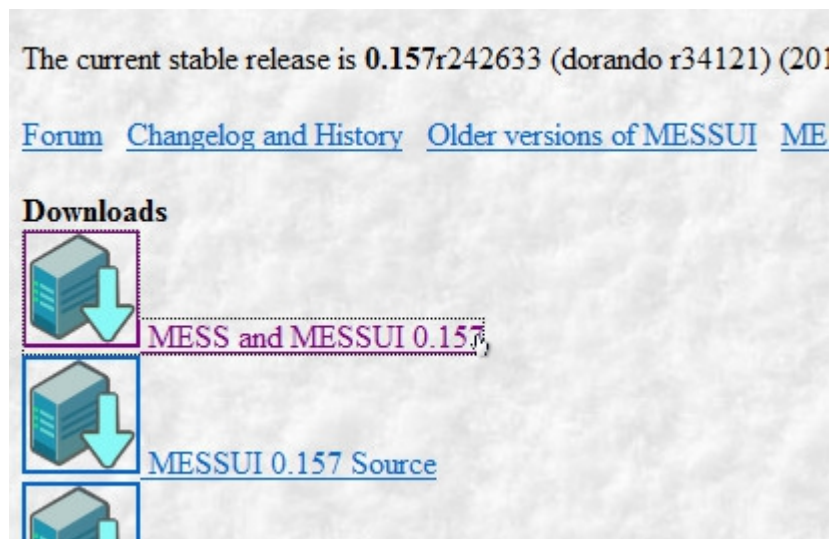

Installing MESSui (Windows)

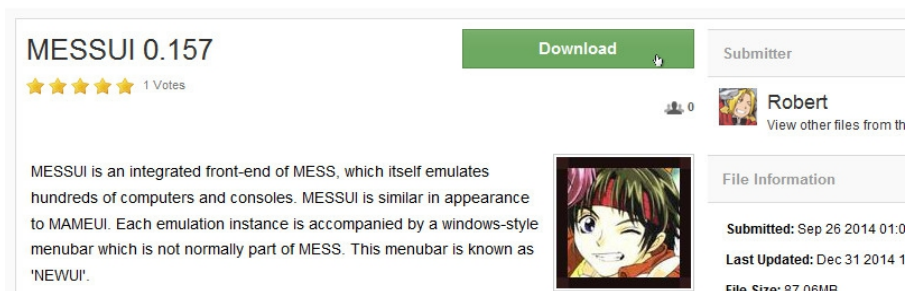

Start a web-browser and navigate to :

Look for the download section

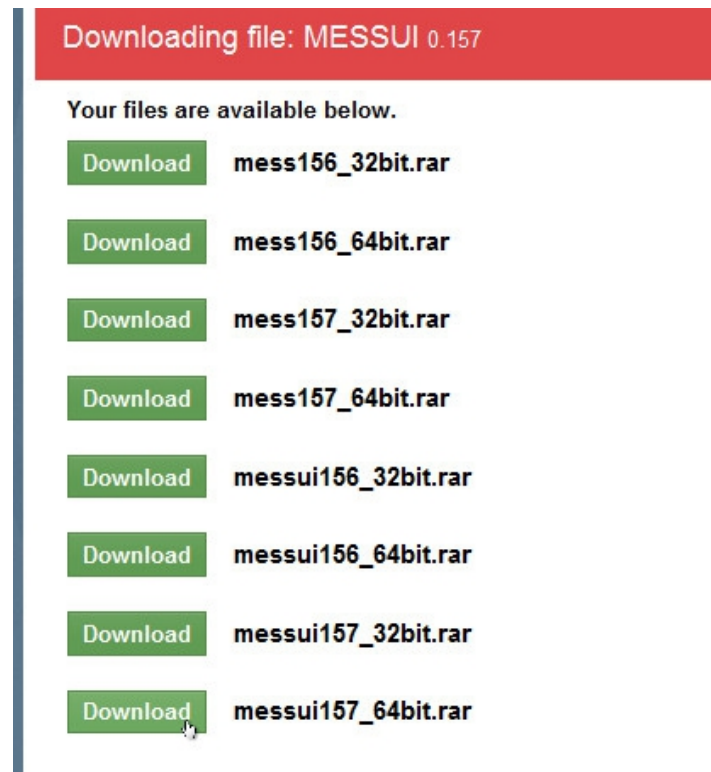

There you can download it

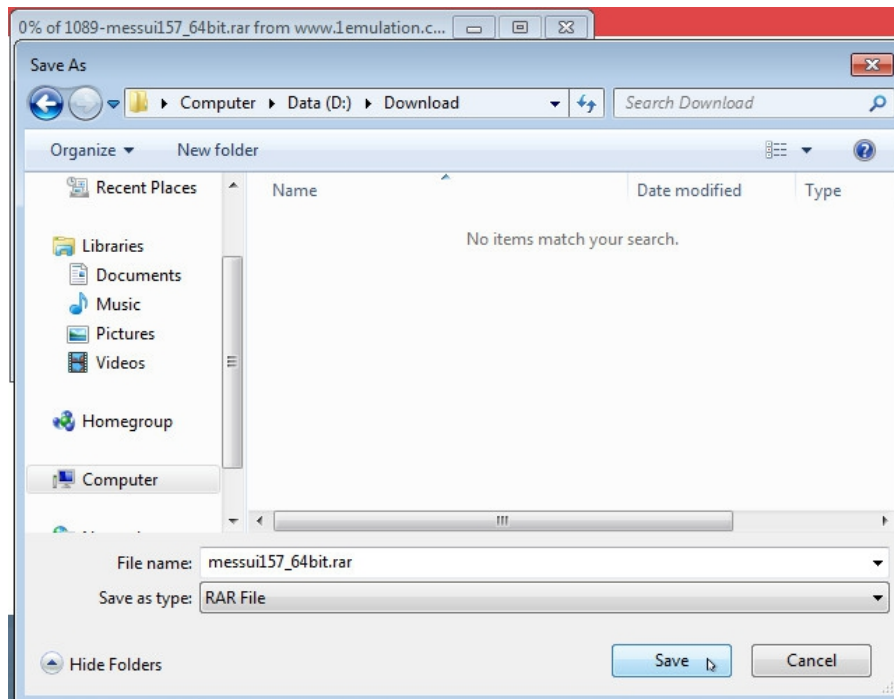

As we want the 64-bit version we choose the latest version number

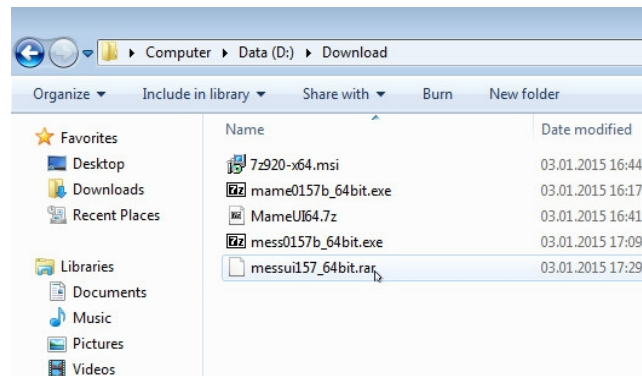

Save it to the download folder

The file is packed with RAR

Right click the file and choose “extract files”

Point it to the mess folder

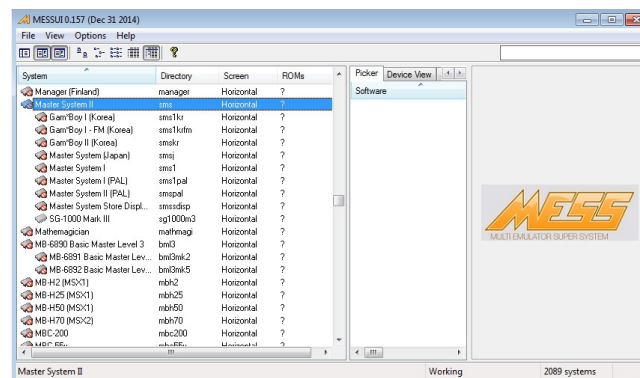

MAME/MESS The Guide

Now should be all files extracted and the folder looks like that

we start the emulator by executing “messui64.exe”. The emulator starts..

Let's test if we can start with this Ui the C-64 too. Search for the c64

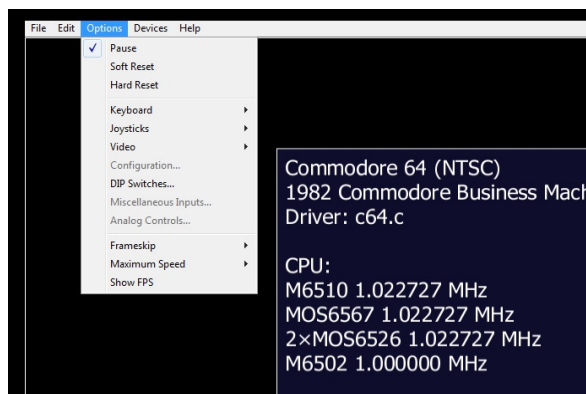

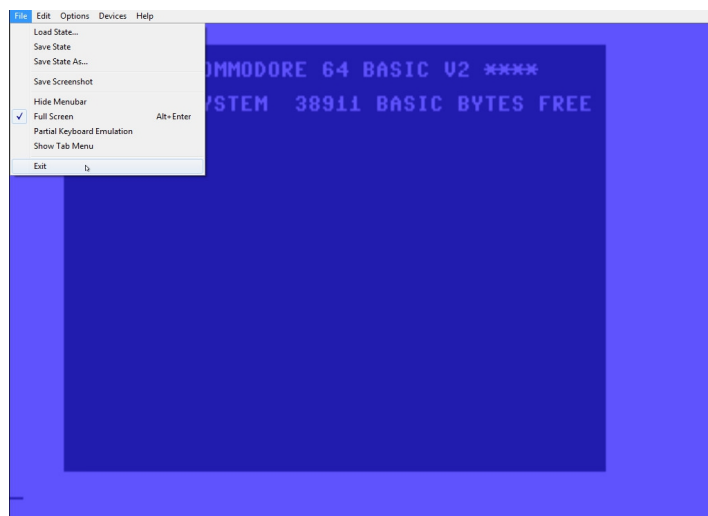

Yes it does start

Note that we have now with this Ui-version comfortable menu drop-down lists available.

The emulator starts the C-64. We exit this emulation with “exit”

MAME/MESS The Guide

We create now a shortcut on the desktop. Drag-and-drop with the right mouse-button the exe to the desktop. From the menu you choose “Create shortcuts here”

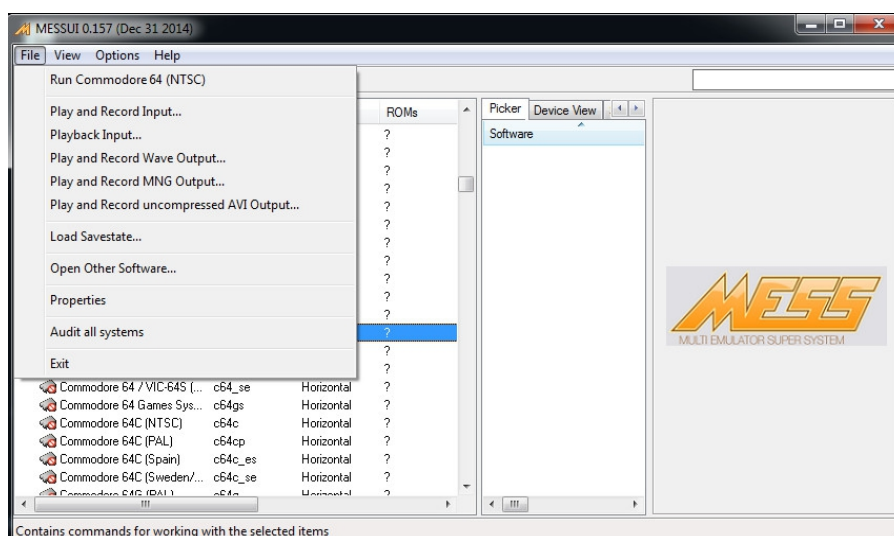

We have now a shortcut on the desktop for MESSui

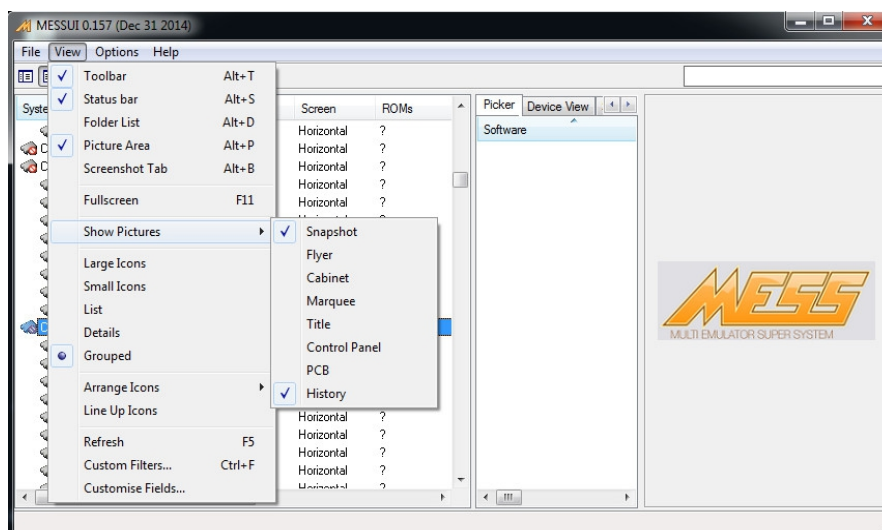

Using MESSui (Windows)

The program is more or less the same as MAMEui. Under “file” you have the opportunity to start the emulator, to record a gameplay or to audit all systems.

Under “view” you can customize how MESSui should look like.

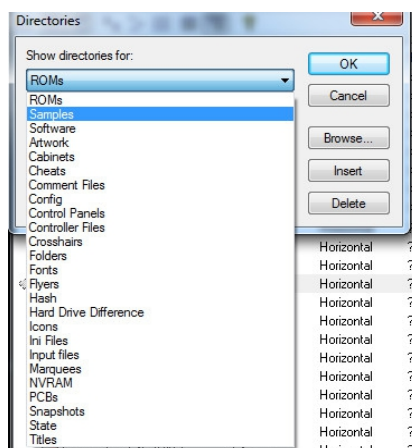

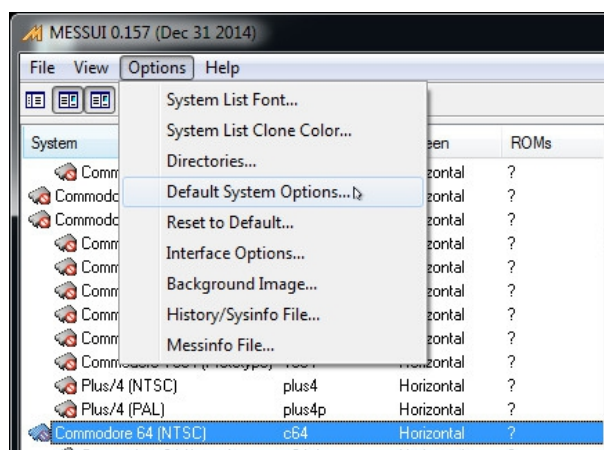

With the “options” you can change settings for MESSui or the emulator.

In “Directories” we can set additional folder-path.

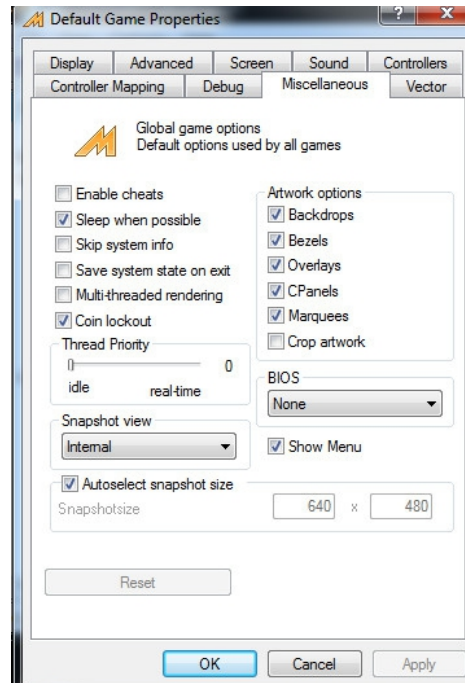

With the “Default Systems Option” we can define settings for all systems.

In this Default options we can for example set display settings or controllers.

We quit this options and don't forget to add the “Softwarelists” as an additional path to the “Directories”.

We have downloaded some games for the TI99-4a Home-computer and saved them to the softwarelists folder under “ti99_cart”. Remember this sub-folder must have this name as it is shown in this list.

We double-click “Donkey Kong” from the Software view for the system “ti99_4a”. The Emulator starts the home-screen that appears all the time you power on the system.

Press “any key” hmmm where is it? Yeah press a key and we can choose the game from the list as number 2.

The game starts...

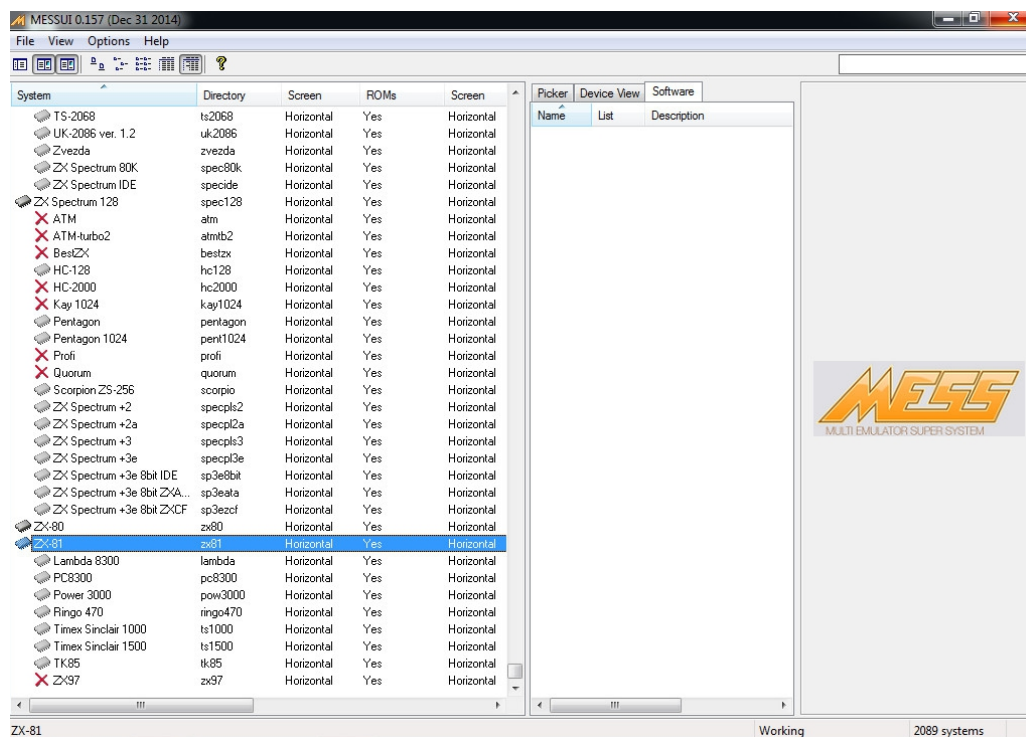

Yeah it looks not the same as the original but it does work.

Quit the Emulator and go back to MESSui.

There are systems listed there that have no games available. You can see it in the “Software” view for example ZX81 has no software available.

MESSUI 0.157 (Dec 31, 2014)

We change now to the “device view” and try to mount that game
“addfamu”

And choose the file “addfamu.zip” from the “softwarelists/snes” folder.

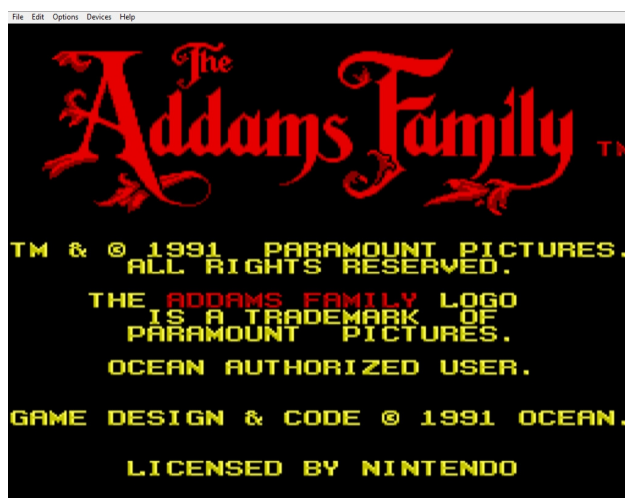

We have now mounted the game and in the “Picker” we double-click the
second entry.

MAME/MESS The Guide

This message tells us that the emulation is not perfect. After “OK” the system starts the game “Addams Family”

Yeah and we can play it too :-)

That was our little excursion into MESS. It is different than MAME. Each system has its own handling. I can not give you an advice that is for every system because a calculator for example is easier to handle than an Apple system. You have to investigate yourself. Try to find some help in the internet. Maybe you want to start a system you had in the past than it is easier for you to understand what you can do with it. In my case it was a TI99-4a. Yes I know you had those cartridges to load first and also for programming you have needed that “Extended Basic” cartridge :-)

Chapter 4: ROMs

In this chapter we are looking what ROMs are and how they are collected. There are several ways to organize his ROM-set and we are looking at the difference. Also special items are covered like CHD-files.

What are ROMs and their status?

ROMs (Read only memory) is a class of storage medium used in computers and other electronic devices to store a game or an operating system. Those ROMs are dumped with special software or hardware devices into files what we call ROM images. With that process we have a copy of the hardware ROMs that MAME/MESS are using. The industry tries to avoid that dumping and adds sometimes copy-protection to their ROMs.

Game: the title of a game

Set: each of the versions of a game.

Clone: version of a game different from the original.

Let's try to explain that with the game 1941:

Name	Description
1941	1941: Counter Attack (World 900227)
1941j	1941: Counter Attack (Japan)
1941r1	1941: Counter Attack (World)
1941u	1941: Counter Attack (USA 900227)

We have the game “1941” with 4 sets and 3 clones. “1941” is the main set.

The game-set “1941” has the following ROMs:

Data					
Version Added:	.145u5				
Last Change(s):					
Roms:					
Name	Set	Size	Flags	CRC	
41em_30.11f	1941	131072	good	4249ec61	
41em_35.11h	1941	131072	good	ddbee5eb	
41em_31.12f	1941	131072	good	584e88e5	
41em_36.12h	1941	131072	good	3cfc31d0	
41-32m.8h	1941	524288	good	4e9648ca	
41-5m.7a	1941	524288	good	01d1cb11	
41-7m.9a	1941	524288	good	aeaa3509	
41-1m.3a	1941	524288	good	ff77985a	
41-3m.5a	1941	524288	good	983be58f	
41_9.12b	1941	65536	good	0f9d8527	
41_18.11c	1941	131072	good	d1f15aeb	
41_19.12c	1941	131072	good	15aec3a6	
buf1	1941	279	good	eb122de7	
ioa1	1941	279	good	59c7ee3b	
prg1	1941	279	good	f1129744	
rom1	1941	279	good	41dc73b9	
sou1	1941	279	good	84f4b2fe	
yi24b.1a	1941	279	good	3004dcdf	
job1.11e	1941	279	good	3abc0700	

Those ROMs (see under “Name” above) are stored in a single zip-file with the name of the set, in our example “1941.zip”. You can also have them unpacked in a subfolder called “1941” but nobody stores it like that ;-)

The clone-set “1941r1” has/needs the following ROMs.

Roms:						
Name	Set	Size	Flags	CRC	SHA 1	
41e_30.11f	1941r1	131072	good	9deb1e75	68d9f91bef6a5c9e1bcbf286629aed6b37b4acb9

job1.11e	1941	279	good	3abc0700	973043aa46ec6d5d1db20dc9d5937005a0f9f6ae	

We see now that this set has also all ROMs included from the main-set “1941”

When we store the ROMs we can decide how they should look like.

Split vs merged vs non-merged ROMs

Where is this information stored ? It seems that MAME knows this and complains if a ROM is missing. With the option “-listxml” we can show us that information. For a better reading we save it into a file called “mame-0157.xml” (btw this is our first created DAT-file ;-))

```
D:\Mame>name64.exe -listxml >mame-0157.xml
D:\Mame>_
```

And open it into notepad and search for “1941”. Here we go ...

```
</game>

  <device_ref name="palette"/>
```

We see now the big difference that “1941r1” is a clone of “1941” and has ROMs from “1941”

All the ROMs that has the flag “merge” are from the main-set (including the name that they have in the main-set).

Okay so far so good. What it is now the difference between merged, not merged and split sets?

If you are using a ROM-Manager like CLRMAMEPRO you have to decided how you want to organize your ROMs. For MAME it doesn't matter if it doesn't find it ROMs in the chosen clone-set it will looks for it in the parent set.

We have three possibilities:

I will show you with CLRMAMEPRO how those “1941” sets looks like with all three possibilities. We are looking at this ROM-Manager in a later chapter.

Non-Merged sets (or unmerged)

I have copied all the 1941 sets to a temp folder. I'm doing now a rebuild with the option “Non-Merged Sets”....

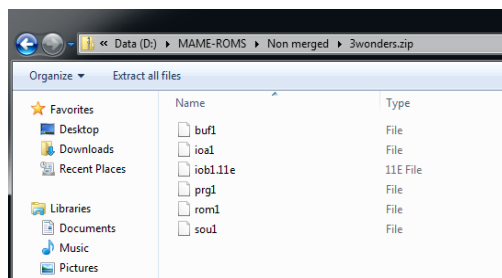

We find the following ROMs in this rebuilt folder:

It seems that a lot of other games have some of the ROMs too in their sets.

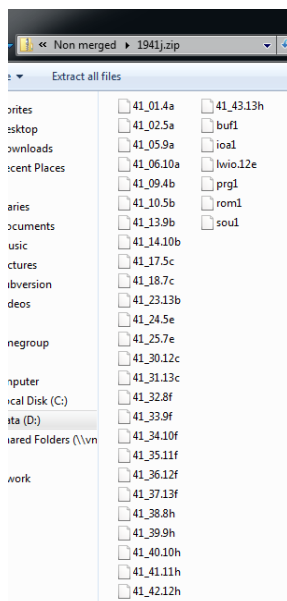

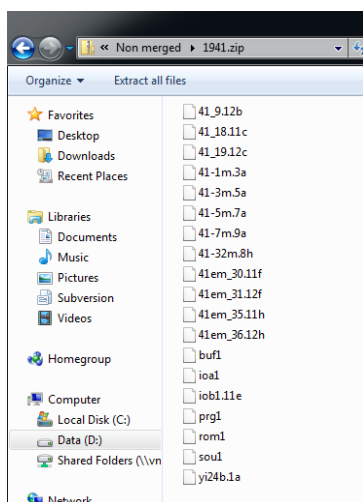

Yeah right ...

Let's forget about all those other sets → I delete them we want only those “1941” sets for investigation. We have those 4 sets available.

Lets open all 4 sets:

Each set has all the needed ROMs inside including the ROMs that are from the parent set “1941”. You can start each game even when you don't have the parent!

Split-sets

Let's do this rebuilding again with the option “Split sets”

Again we have those 4 sets in our rebuilt folder but wait look at the size of each file (compared to “Non-Merged Sets”).

Open those 4 sets again

We see that we have only the ROMs inside a set that is from that set. That means that we NEED the parent ROMs when we want to play a clone (because only with clone + parent we have a complete set).

Merge sets

Let' do our rebuilding again with the option “Merge sets” chosen.

Yeah wow what's this?

Only one file and a little big in size? Open this zip file and you will find the answer.

The parent set “1941” has ALL the ROMs including all clone-sets inside this “1941.zip” file.

Compared all three possibilities

Each way to store the ROMs has advantages as well as disadvantages. It's your decision how you store the ROMs.

Non-Merges-Sets

- + Each set is complete and can be used for gaming
- + It has no dependencies → if one zip is corrupt the other sets are working
- - Needs more space because all clone have also the parent ROMS inside

Split Sets

- + This needs less space than Non-merged sets
- + all clone are in separate zip-files and have only the needed ROMs inside
- - It has dependencies → it needs all the time the parent set

Merge Sets

- + needs less space
- + has the minimum of files in the ROM folder
- + If two sets shares a common file it include it once.
- + no dependencies → everything is in one zip-file
- - file handling is difficult → no clone-file exists only the parent set exist as one zip-file
- - if you only want to collect parent games you have wasted disc space → it included all the clone sets too inside this zip-file.

I store my ROMs as split-sets. Be always sure before you rebuild/scan or join a torrent that you have the SAME wanted option set.

Status of ROMs/Games

You have maybe noticed that ROMs or games have status information available.

For example “1941” has this status in the emulation.

```
</port tag=":IN0">
</port>
<port tag=":IN1">
</port>
<port tag=":DSWA">
</port>
<port tag=":DSWB">
</port>
<port tag=":DSWC">
</port>
<driver status="good" emulation="good" color="good" sound="good" graphic="good" savestate="supported"/>
</game>
<game name="1941j" sourcefile="cps1.c" cloneof="1941" romof="1941">
<description>1941: Counter Attack (Japan)</description>
<year>1990</year>
<manufacturer>Capcom</manufacturer>
```

It is noticed as “good” and it works very well. Others are flagged as “imperfect” or “preliminary” (not working).

```
</port>
<port tag=":DSW2">
</port>
<driver status="imperfect" emulation="good" color="good" sound="good" graphic="imperfect" savestate="supported"/>
</game>
<game name="7mezzo" sourcefile="magicfly.c">
<description>7 e Mezzo</description>
<year>1987</year>
<manufacturer>Atl unknown</manufacturer>
```

In MAMEui you see this status at the bottom in the status bar.

Information about a ROM is also in the XML-File available.

For example “baddump” means that the ROM was dumped but not perfect.

```
om name="5105.prom-u14" size="2048" crc="17807a05" sha1="bd99f5beab0155f6e4d2fab2fa5f4e147c5730d5" region="maincpu" offset="";

```

→ And NOT available, so nobody has it.

**! Be sure that you are not asking in forums for playing games that are
• stated as “preliminary” or “not working”**

What are CHD files?

Some games in MAME needs additional Hard-disc-files to run. A separate tool is available for handling them. It is in the MAME folder and called “chdman.exe”

With the command-line you can get some more info what is possible with it.

```
C:\Windows\system32\cmd.exe

D:\Mame>chdman -?
chdman - MAME Compressed Hunks of Data (CHD) manager 0.157 (Dec 31 2014)
Usage:
  chdman info: displays information about a CHD
  chdman verify: verifies a CHD's integrity
  chdman createraw: create a raw CHD from the input file
  chdman createhd: create a hard disk CHD from the input file
  chdman createcd: create a CD CHD from the input file
  chdman createld: create a laserdisc CHD from the input file
  chdman extractraw: extract raw file from a CHD input file
  chdman extracthd: extract raw hard disk file from a CHD input file
  chdman extractcd: extract CD file from a CHD input file
  chdman extractld: extract laserdisc AUI from a CHD input file
  chdman copy: copy data from one CHD to another of the same type
  chdman addmeta: add metadata to the CHD
  chdman delmeta: remove metadata from the CHD
  chdman dumpmeta: dump metadata from the CHD to stdout or to a file

For help with any command, run:
  chdman help <command>

D:\Mame>_
```

Just to be exact this tool is not used for playing but it is an add-on tool that can check your CHD-files for errors for example.

Store the CHD-file in a subfolder in ROM folder that is named like the game.
For example:

```
roms\  
  area51.zip  
  area51\  
    area51.chd
```

You need the corresponding ROMs for the game to work. The name of the CHD must not all the time be the same as the folder. For example, the CHD for Beatmania is named 753jaa11.chd. It would go in a directory called "bm1stmix".

! Those CHD-files are already compressed and you don't have to zip them.

We have a CHD-file available for doing some “testing”

```
D:\Mame>cd roms\2spicy  
  
D:\Mame\roms\2spicy>dir  
Volume in drive D is Data  
Volume Serial Number is A698-D03C  
  
Directory of D:\Mame\roms\2spicy  
  
25.01.2015  14:43    <DIR>          .  
25.01.2015  14:43    <DIR>          ..  
07.12.2014  06:05          3'317'217'136 dup-0027a.chd  
               1 File(s)  3'317'217'136 bytes  
               2 Dir(s)  469'963'558'912 bytes free  
  
D:\Mame\roms\2spicy>
```

For showing some information about this CHD-File use the “info” parameter:

```
C:\Windows\system32\cmd.exe  
  
D:\Mame>chdman info -i roms\2spicy\dup-0027a.chd  
chdman - MAME Compressed Hunks of Data (CHD) manager 0.157 (Dec 31 2014)  
Input file:  roms\2spicy\dup-0027a.chd  
File Version: 5  
Logical size: 3,321,888,768 bytes  
Hunk Size:    4,096 bytes  
Total Hunks:  811,008  
Unit Size:    512 bytes  
Total Units:  6,488,064  
Compression:  lzma (LZMA), zlib (Deflate), huff (Huffman), flac (FLAC)  
CHD size:     3,317,217,136 bytes  
Ratio:        99.9%  
SHA1:         dalaacee9e32e813844f4d434981e69cc5c80682  
Data SHA1:    68aed9b52287fb2d060f3a98ed9db2e26c1b0e97  
Metadata:     Tag='GDDD' Index=0 Length=35 bytes  
              CYLS:8448,HEADS:16,SECS:48,BPS:512.  
  
D:\Mame>
```

There you can see what version is this CHD-File and some other information like the checksums for it.

With the option “verify” we can check the integrity of this CHD-file.

```
D:\Mame>chdman verify -i roms\2spicy\dup-0027a.chd
chdman - MAME Compressed Hunks of Data (CHD) manager 0.157 (Dec 31 2014)
Raw SHA1 verification successful!
Overall SHA1 verification successful!

D:\Mame>
```

Sometimes this tool “chdman.exe” gets an update and we must convert the CHD-files to the new format. At the moment we are at version 5.

With this command you can update a CHD-File to a new one.

```
C:\Windows\system32\cmd.exe

D:\Mame>chdman copy -i roms\2spicy\dup-0027a.chd -o roms\2spicy\newname.chd
chdman - MAME Compressed Hunks of Data (CHD) manager 0.157 (Dec 31 2014)
Output CHD:   roms\2spicy\newname.chd
Input CHD:    roms\2spicy\dup-0027a.chd
Compression:  lzma (LZMA), zlib (Deflate), huff (Huffman), flac (FLAC)
Hunk size:    4,096
Logical size: 3,321,888,768
Compression complete ... final ratio = 99.8%

D:\Mame>
```

Name	Date modified	Type
dup-0027a.chd	07.12.2014 06:05	CHD File
newname.chd	08.02.2015 15:28	CHD File

We have created a new CHD-file called “newname.chd” with the version number 5.

Download ROMs

There are different website where you can download ROMs. One of them is Retroroms.net.

You must create an account there for downloading ROMs. After you have logged on on the website you can download stuff by choosing Downloads in the navigation menu.

Now you are in the download section and can download what you want.

Index of /downloads

bda.retroroms.net/downloads/

! Please note: Retroroms.net permit 1 file at the time to download otherwise you are blocked. If you want to download a lot of files please use a download manager!

Download CHD from Retroroms.net

We can download also CHD-files from Retroroms.net. They have splitted those file into smaller RAR-pieces. The reason is simple, if you download a huge file and you have a disconnect you could maybe not “resuming” again and you have to start again from the beginning. That's the reason why they split those file into small 20MB RAR-pieces. If you have an interrupt you only have to download again the missing/corrupt parts again.

Lets have a look at a CHD-folder

Name	Last modified	Size	Description

In this folder are a lot of RAR-pieces, a md5-file and a txt-file.

We can download them now with the web-browser but it takes a lot of time to click each file manual. That's not comfortable and I show you now how to download them with a Firefox plug-in.

I have not installed Firefox in my environment so let's do that first.

Download the installer from the Firefox-site

Save it to our download folder

And start the installation ..

Choose “custom” ...

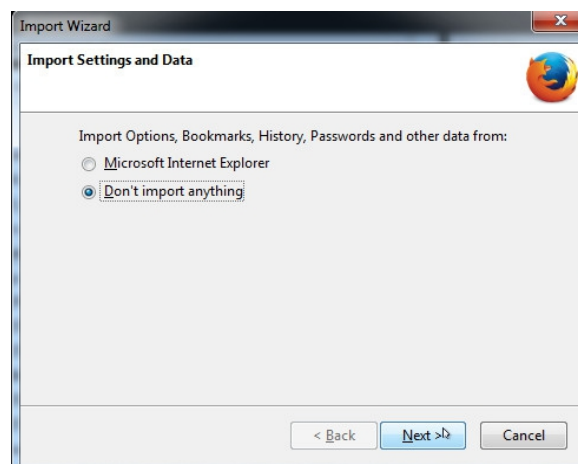

...because we want to install it to our data drive:

And import “nothing”

Now after the installation we start it and search for “DownThemAll”

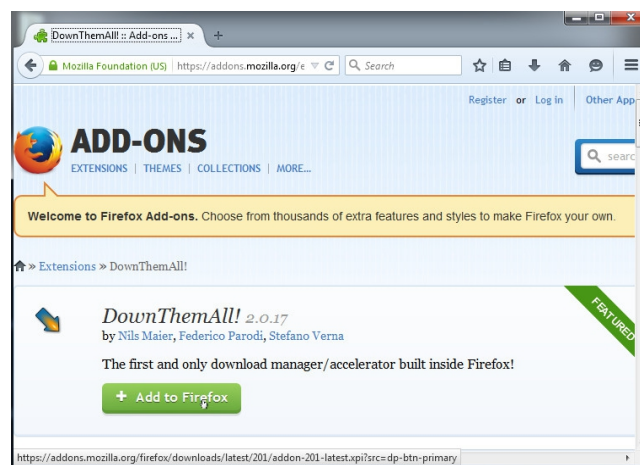

First link is where we can download the download-manager plug-in

Choose “+ Add to Firefox”

And install the plug-in

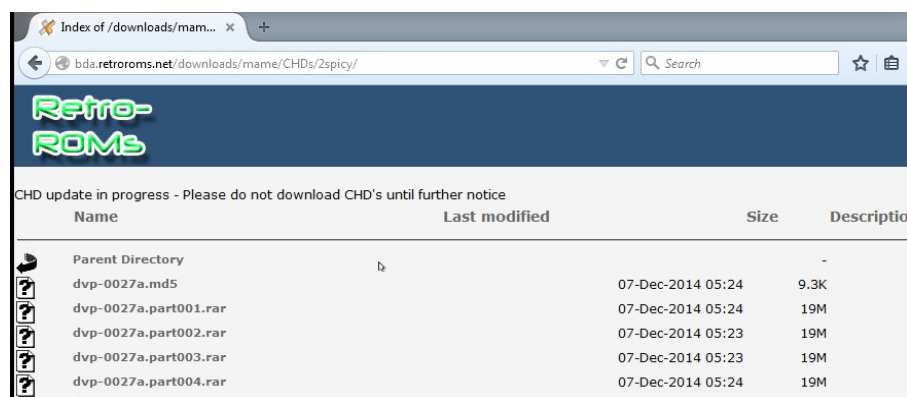

At the end you must restart the browser

Now we go to the Retroroms.net with the Firefox browser

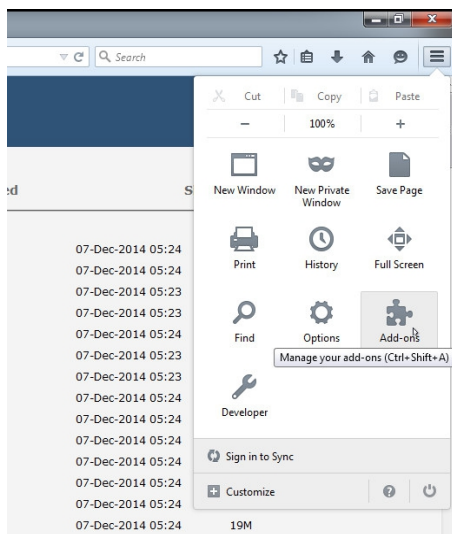

Open the download page and navigate to the 2spicy CHD folder

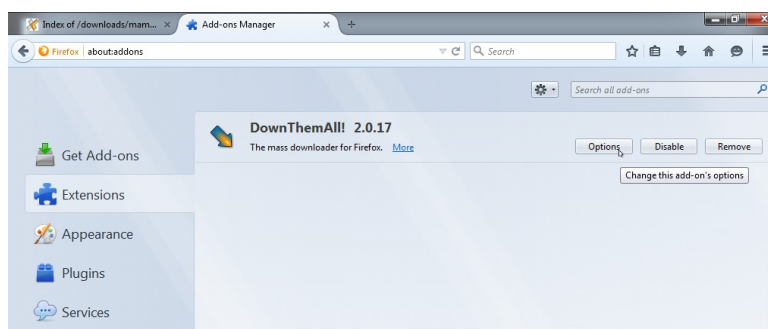

As I have already mentioned Retroroms.net does only permit download 1 file at the time. We must configure our plug-in to this limitation.

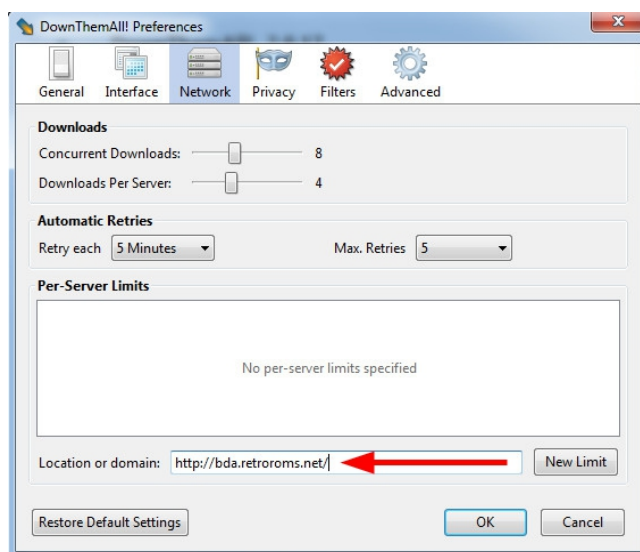

Open the Add-ons

In the DownThemAll plug-in click the options

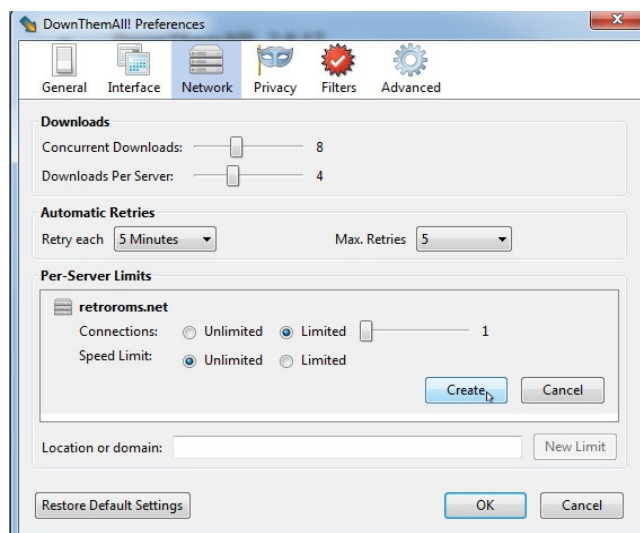

Add the address from the download folder into this field

Click “New Limit” and set the “connections” to 1 for this Site. Click “create”

We have now configured the limitation for this site in the download-manager plug-in. (Click OK)

Let's go to the download page and do a right-click on this page. In the context menu choose “DownThemAll”.

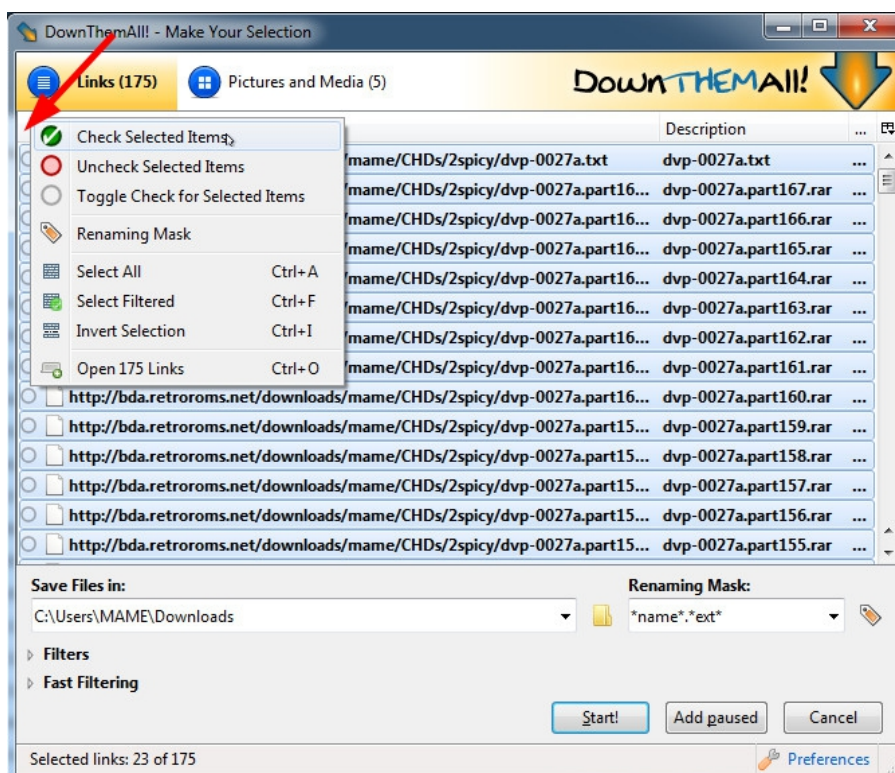

The download-manager should open with all the links.

We must choose now all the files we want to download. Right-click on this place and choose “Select all”.

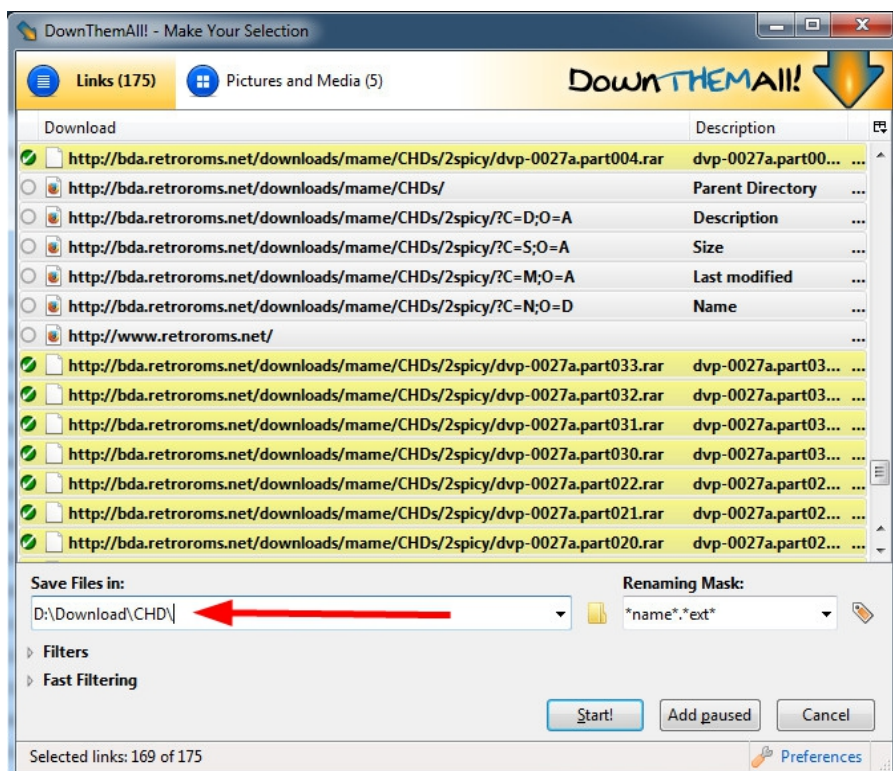

Click again on this place with the right mouse-button and choose “Check Selected Items”

Now we have chosen all files for downloading. Note that this list has also some web-page related items there. De-Select this one we don't want to download them.

Set the download location to a new folder called “CHD”

Now click “Start!” and it begins to download all this files. Note that 1 file is downloaded at the time :-)

Because this CHD is big it takes a while to download all files. At the end every file should be downloaded.

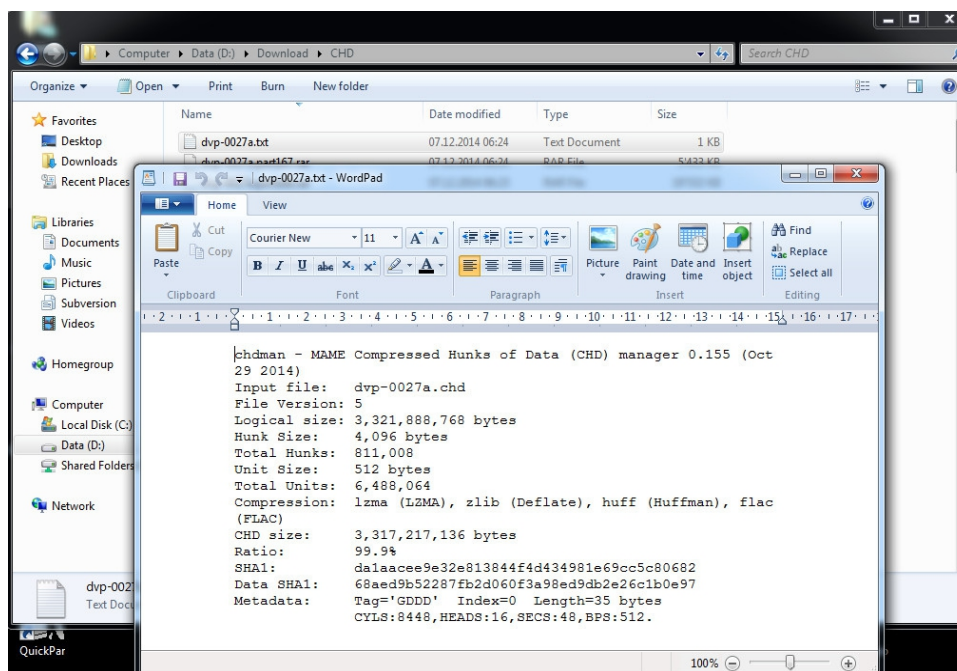

In the download folder are now all files. A lot of RAR-pieces, a md5-file and also a txt-file.

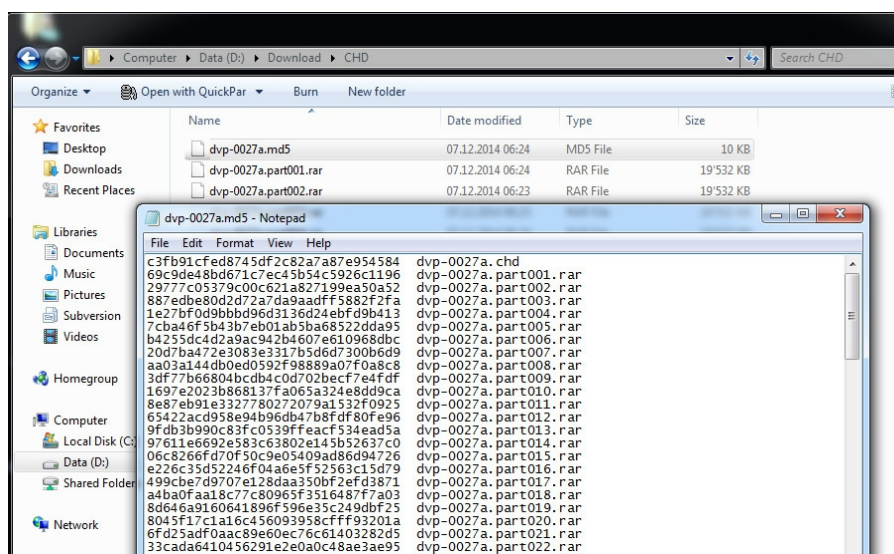

We open the txt-file for looking at the content.

It has information about the CHD-file. It was created with the MAME-tool “chdman.exe”.

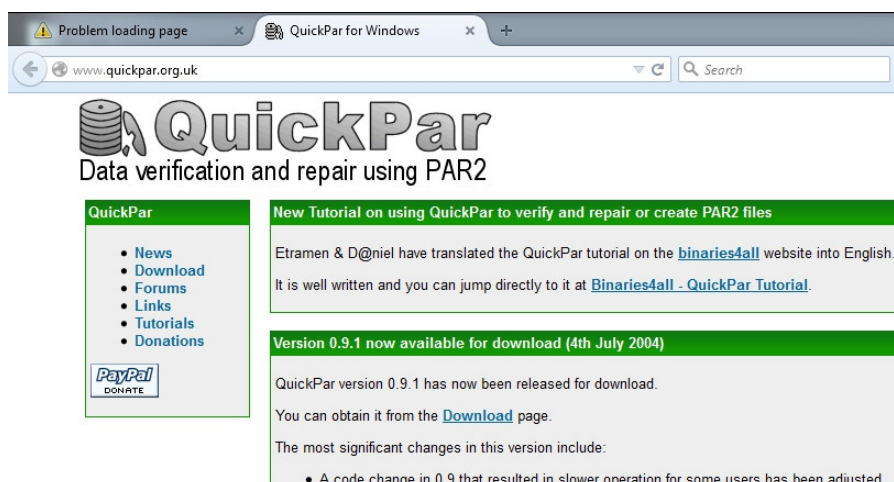

Now open the md5-file:

This file have for each file md5 checksum information. Each file has it own individual hash-code that is build with a algorithm. If you want to know more about the md5 algorithm visit <http://en.wikipedia.org/wiki/MD5>

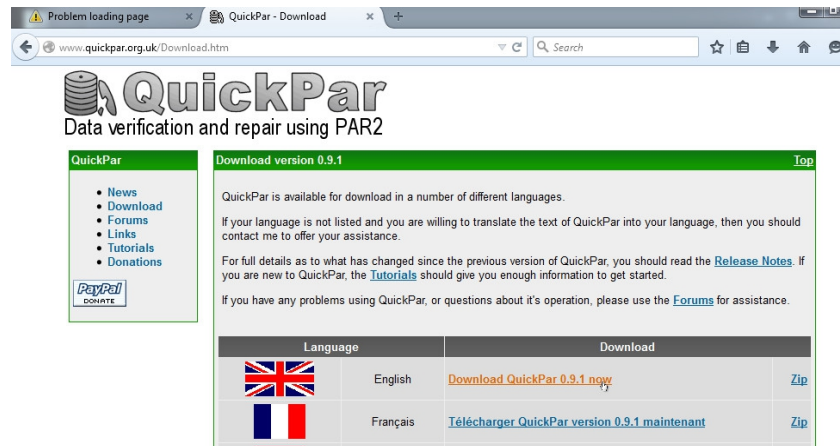

We can check now our downloaded files if they are the same as they are on the web server. We can verify if all the downloaded files are complete.

I'm using this little too for checking files with a md5-file. Open a browser and go to ...

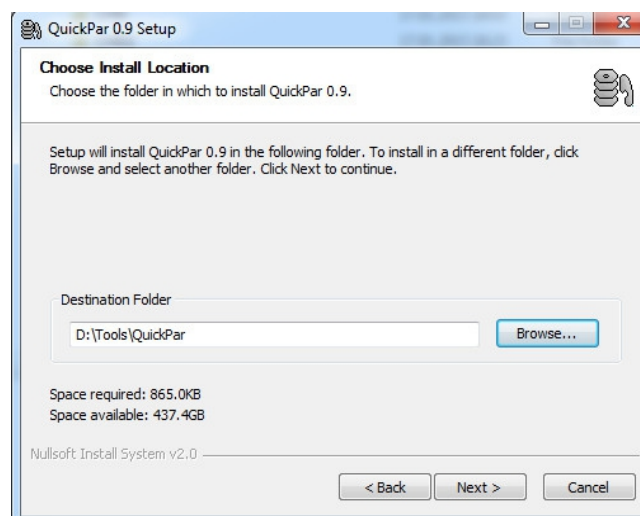

Download the installer

And install it

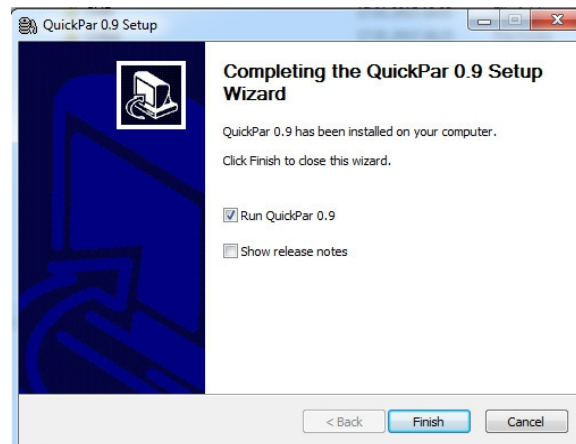

Choose our data-drive as the destination folder

At the end of the installation we start the program.

In the program options we select everything in the Integration section.

We can close now the program with “Exit”

In the download folder we can now double-click the md5-file

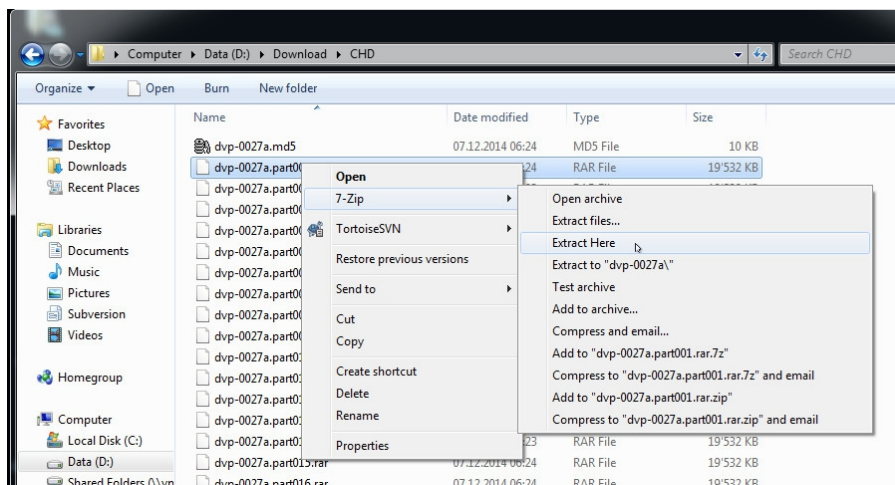

The program “QuickPar” should start and begin to check all the files and compares them with the md5-checksum in the file.

After everything is checked you see that one file is “missing”, all the others should be green. Otherwise download the corrupt/parts again from the web page.

The md5-file has been created while the original CHD-file exists.

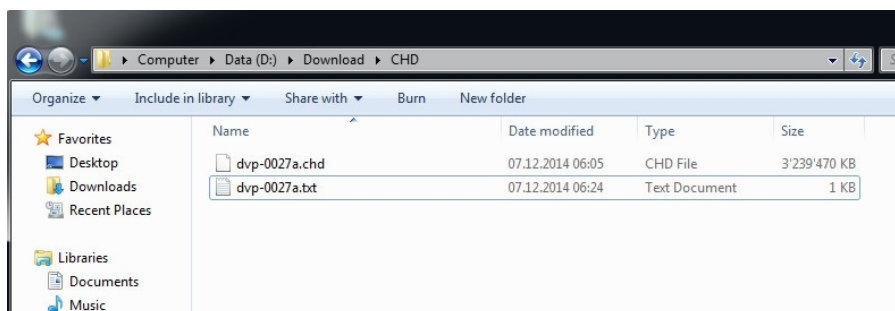

Let's choose the first RAR file with the name “dvp-0027a.part001.rar” and right-click it and choose “extract here”

We have now extracted the CHD-file and now start the md5-file again by double-clicking. Now the result should be “Repair not needed”.

Everything is fine now we can delete now all rar-parts and the md5-file.
Do not delete the CHD and the txt-file!

We copy now the “chdman.exe” from the MAME folder

..to the download folder. We are now verifying the CHD-file with the chdman.exe.

Open a cmd-window, navigate to this folder and execute the following command “chdman.exe verify -i dvp-0027a.chd”. The program “chdman.exe” checks the CHD-file for errors and verify the hash-code. It should tells you “Successful”

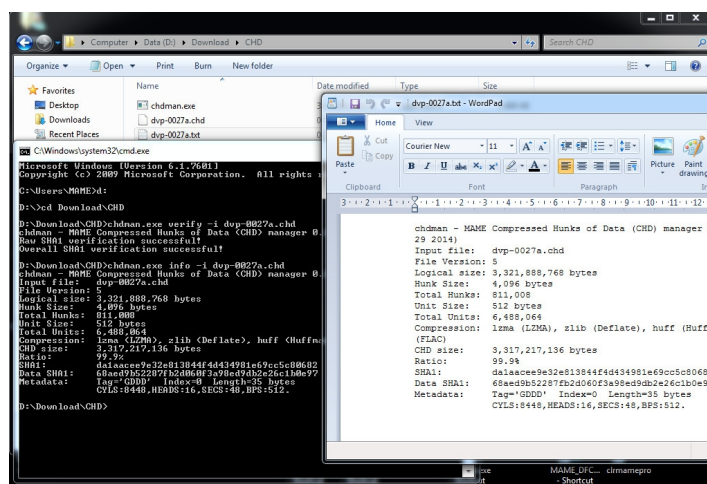

With the option “info” it displays you information about this CHD-file.

Yes sure you have already seen that information somewhere else. Right it is in the txt-file. It should have the same information as it is displays in the cmd-window:

Let's close the WordPad and the cmd-window. We can delete now also the txt-file as it is not needed by MAME.

Now create a folder called “2spicy” and move the CHD-file into that folder.

Move that folder “2spicy” to the mame\rom folder if you want to use it with MAME.

How do we know how the folder name is? When you are scanning your set (See chapter “CLRAME”) it will list the missing chd with the folder name:

That's it we have download our first CHD-file from Retroroms.net. If you need a lot of CHD-files it is maybe a better way to use torrent-files from other websites.

About the versions number

What does happens if we have MAME Version 0.158 installed and our ROMs are still at version 0.157? You should should try to have the same version. Otherwise some games does not work. Added or renamed ROMs would be listed as missed. It is the same also for the add-ons pictures. Sometimes also a set will be renamed and in this case no picture is displayed.

Chapter 5: Other Tools

Installing a front-end

There are several front-end available for MAME/MESS. One of them is EmuLoader.

Start a web-browser and go to <http://emuloader.mameworld.info/>

Download the “binary full” version

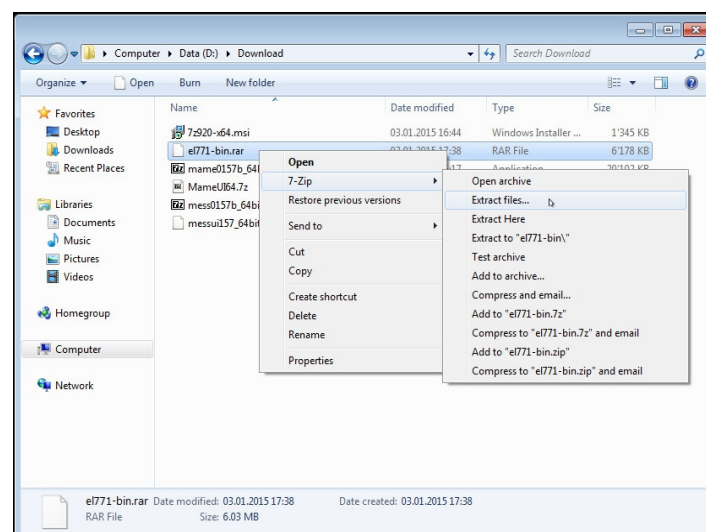

Save it to the download folder

Here we are

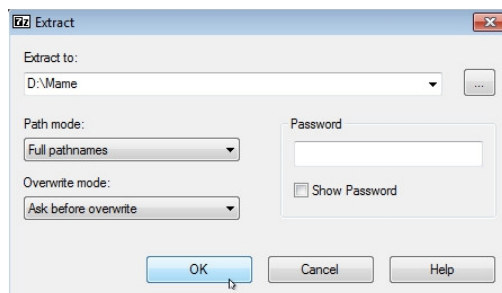

Extract the RAR-File by pressing the right mouse-button and choose
“Extract files”

we want use it with the MAME and extract it to the mame folder.

! This front-end can handle different emulator like MAME and MESS. If you use it for other emulators it is better to install it to an own folder.

We have now the executable within the mame folder.

We start the front-end with the executable

Starting the first time a wizard starts

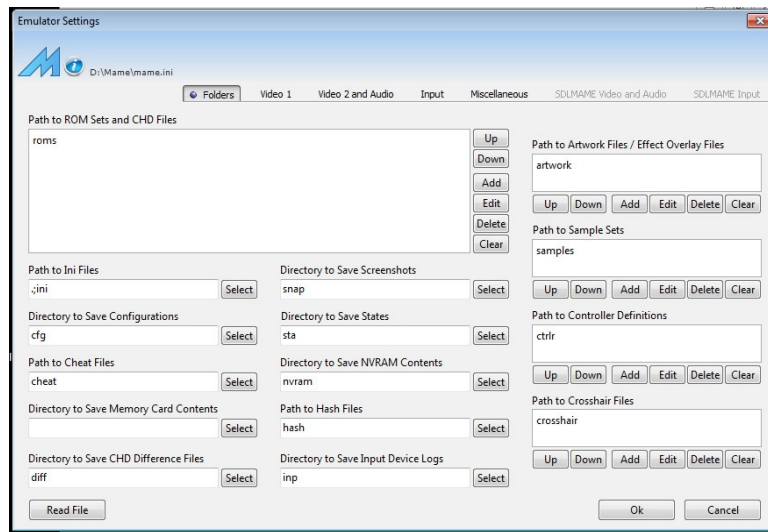

As we want use it for the MAME Emulator point it to the executable

! This is a UI-program it is used for work only with command-line emulators.

Leave the folders default for now.

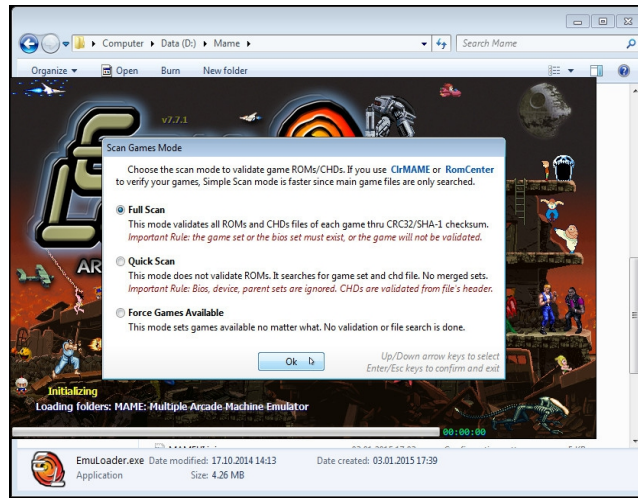

! As we have installed the EmuLoader into the same directory as MAME we don't have to change all the folders. If you are going to use EmuLoader for different systems it would be better to extract it to a separate own folder.

Click “OK”

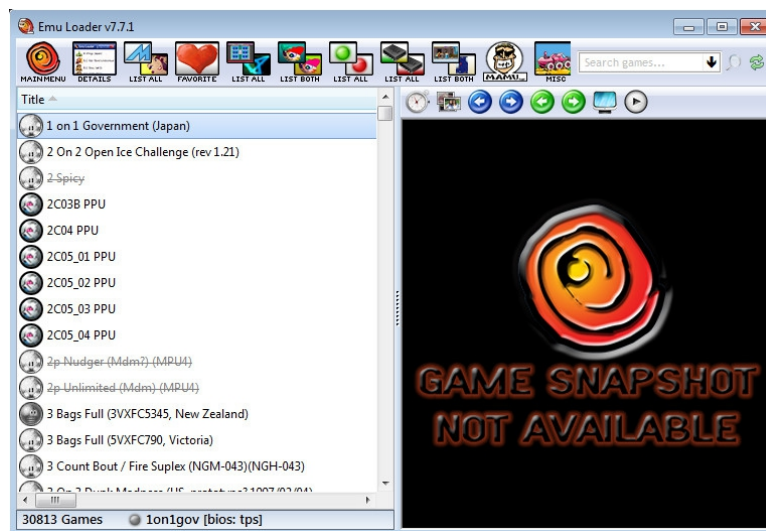

For the first time it will scan the folders for available ROMs.

The scan can takes some time

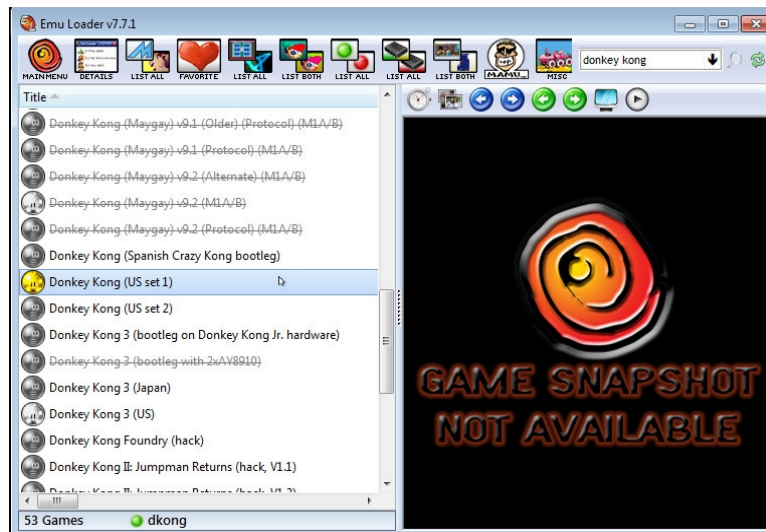

The front-end has started

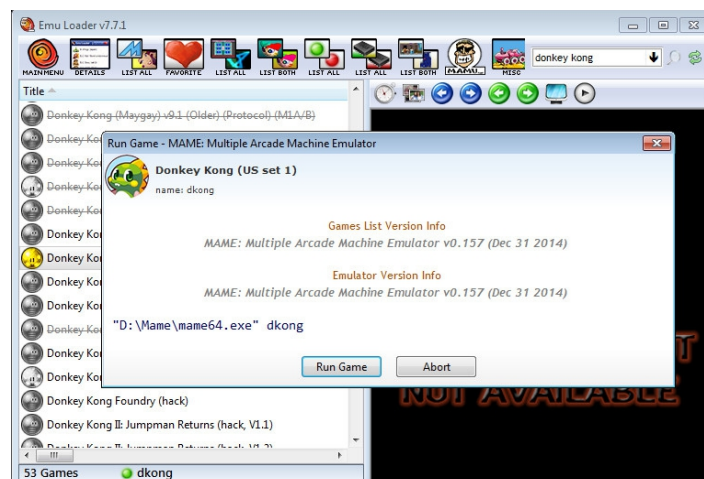

Testing? Yes sure. Search again for “Donkey Kong”

Start it

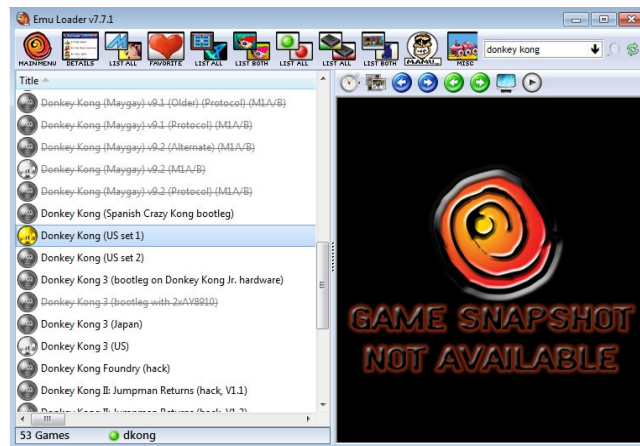

yeah it works

With “esc” you exit the game (MAME)

Okay lets create a shortcut for EmuLoader. Drag-and-drop the exe with the right mouse-button to the Desktop. Choose “Create shortcuts here”

yeah great, ready for playing :-)

Using a front-end

In EmuLoader you can set a lot of options, some of them are for the emulator and others are only how the EmuLoader looks like.

Start EmuLoader

You can set a lot of details under “Main Menu”. One of them are the settings for the emulator itself (Default settings).

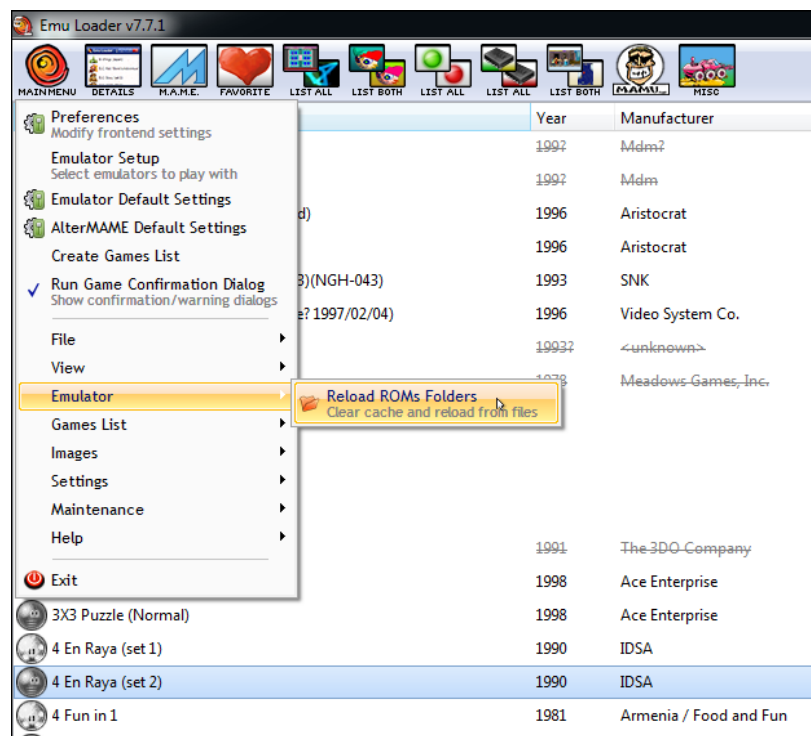

Here you can set for MAME all default-Settings.

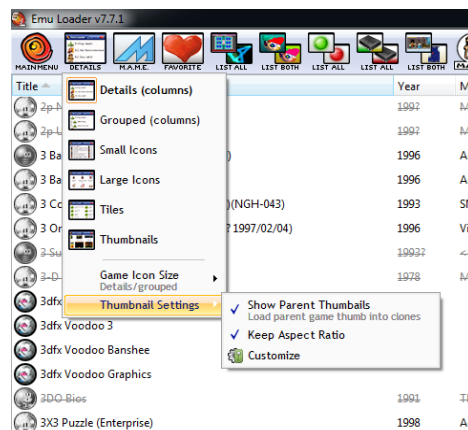

If you have updated your MAME, verify that the exe path is still the same. If you have updated/added ROMs to your ROM-folder be sure that you let EmuLoader do a new scan to refresh his cache.

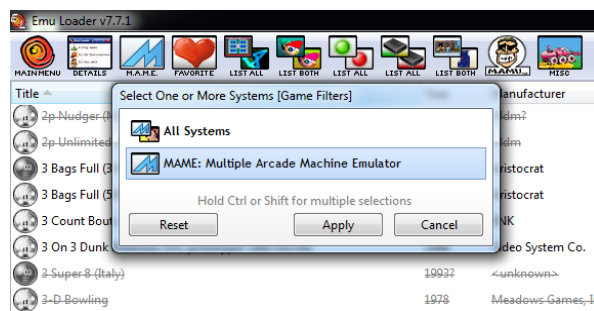

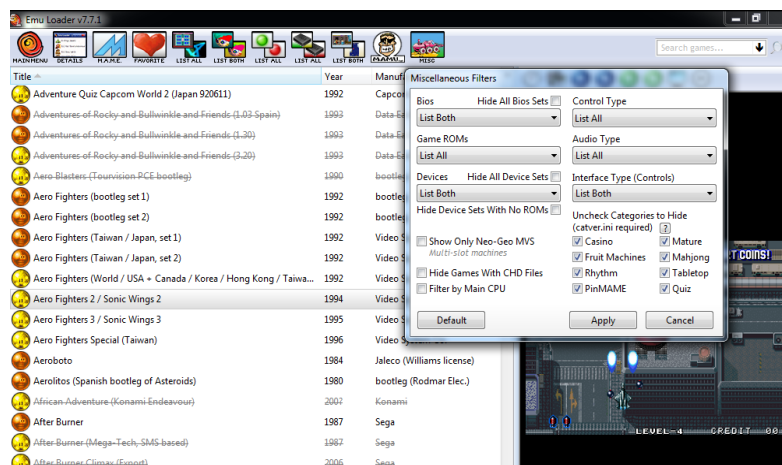

Under “details” you can change the EmuLoader view.

As this is a Front-end and can include more than one emulator (MESS) you can choose in this “Game Filter” which emulator it should displays.

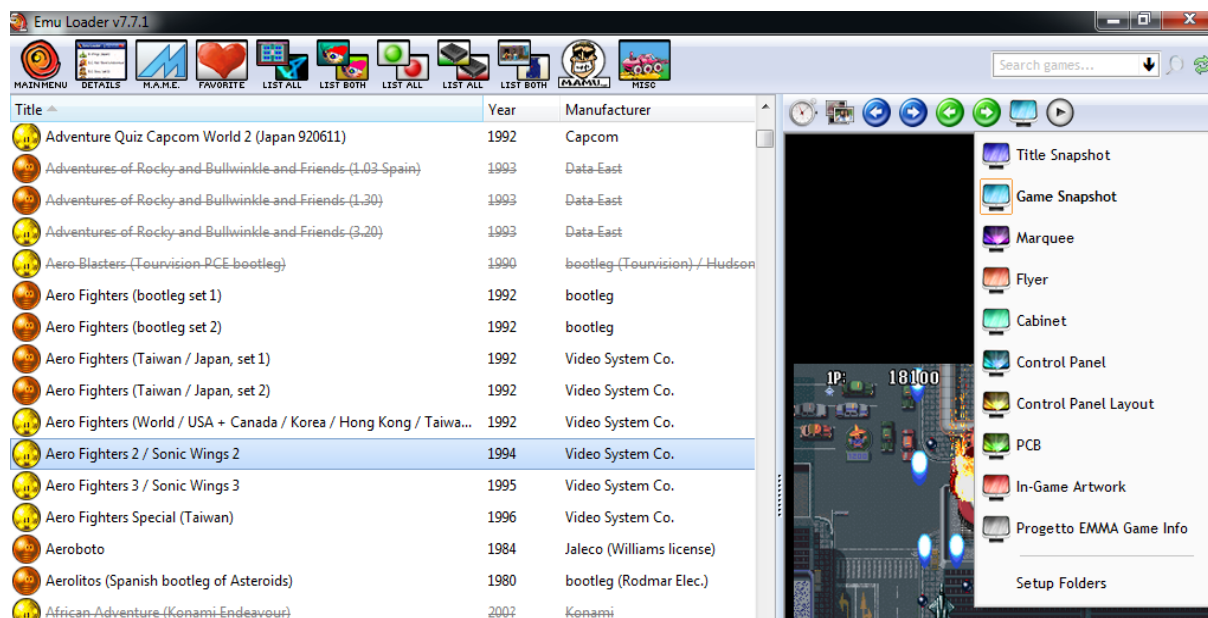

All the other options are for setting up a custom view. You have to play around what you want to have listed. Under “Misc” you can also set some special “view” options :-)

With this EmuLoader it is also possible to display more picture of a system/game like a “control Panel” or a “PCB”.

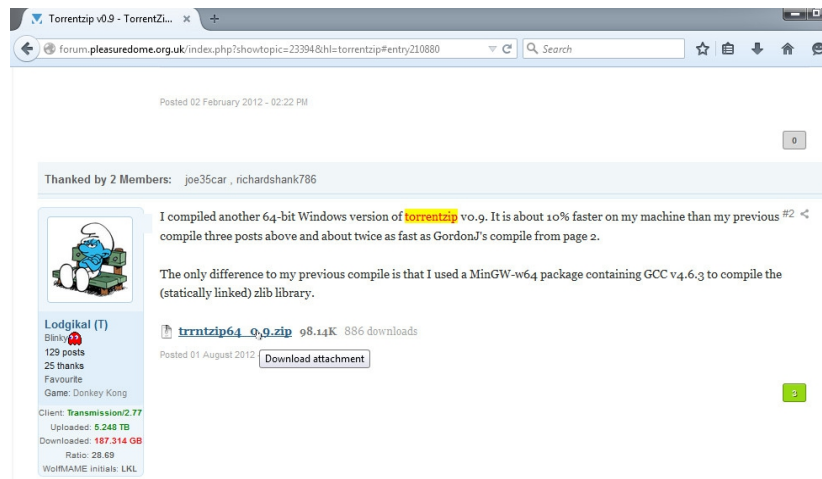

Installing torrentzip

Sharing ROMs with a torrent is only possible since some nice people has developed torrentzip. With the normal ZIP it was not possible to share the same zip with the same ROMs inside to others without to download it again. With torrentzip it is possible that I can create a zip-file that use a machine independent algorithm to compress the file. The result is that this zip-file is 100% the same regardless on which machine it is created. So all the people who have this file can join the torrent without downloading it again.

Be sure that you rebuild your set to the same version that the torrent is for. Also keep in mind that it should have the same structure (merged/split/unmerged).

Let's download the torrent-zip program from the internet (do a search for it). I have a 64-bit Windows → in that case I need the 64-bit version

Extract the downloaded file to a folder

We move the extracted exe to ...

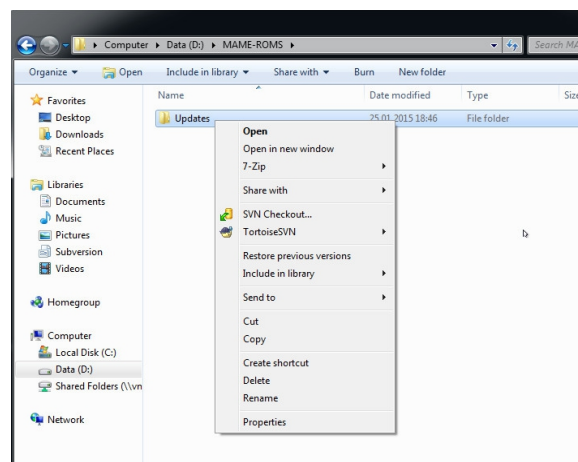

..to a new created folder “torrentzip” in our tools folder.

As this is also a command-line tool we can check if it does work with the option “-?” to display the version.

And how to use it? I don't want to start a cmd-windows and execute it with the parameters. Would it be not nice to have it available in a context menu of a folder?

We want that! Create a file in the torrentzip-folder called “Register...txt”

Open the file and add the following lines into it:

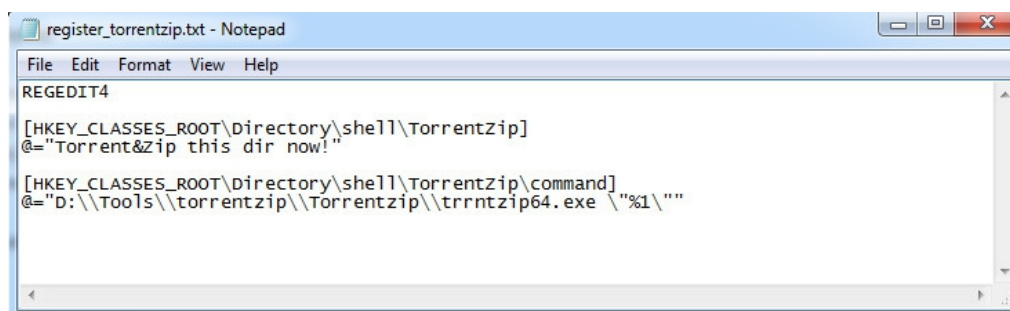

```
REGEDIT4
```

```
[HKEY_CLASSES_ROOT\Directory\shell\TorrentZip]
```

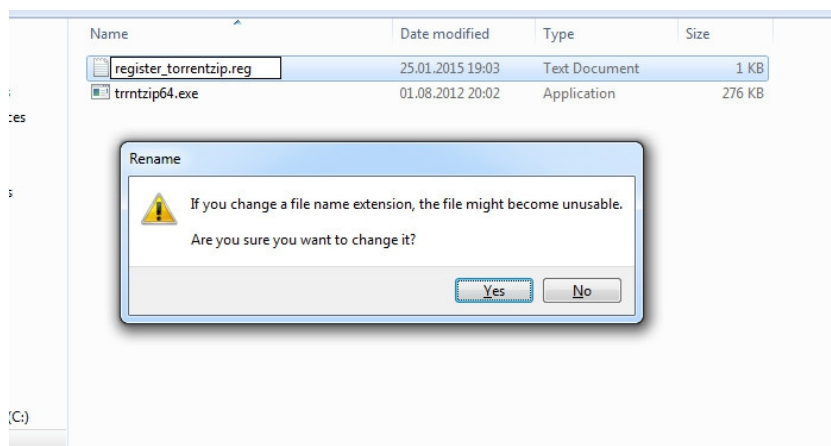

```
@="Torrent&Zip this dir now!"
```

```
[HKEY_CLASSES_ROOT\Directory\shell\TorrentZip\command]
```

```
@="D:\\Tools\\torrentzip\\trrntzip64.exe \"%1\""
```

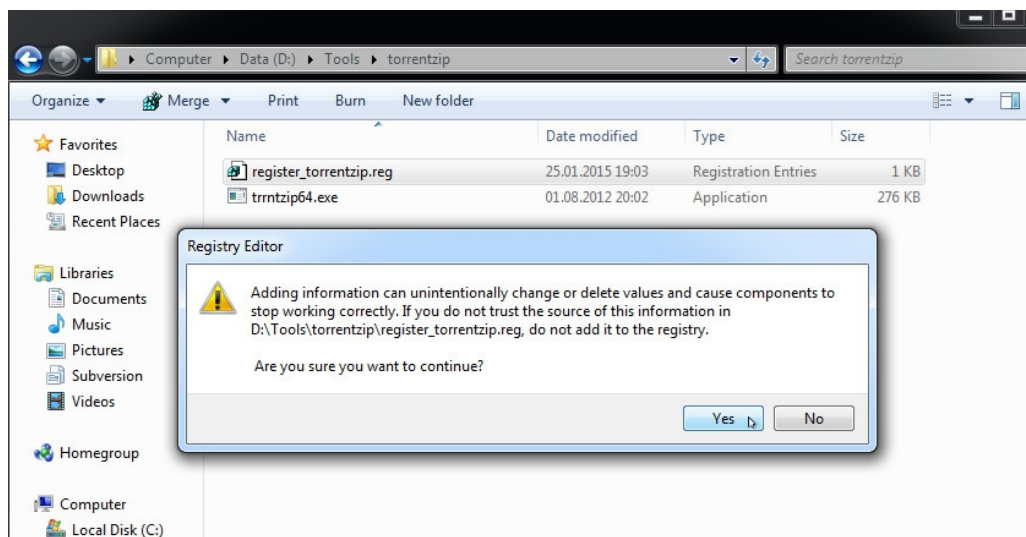

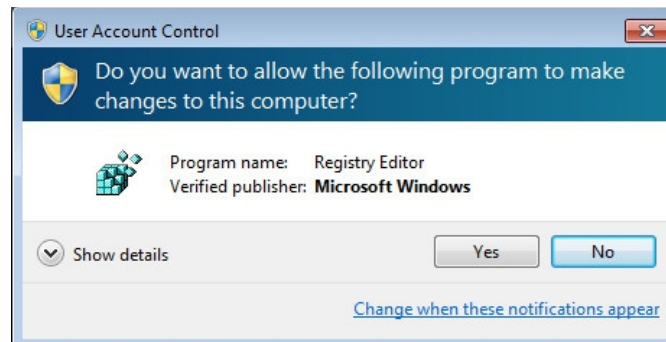

Save the file and rename it to a “.reg” file.

Now import this reg-file into your registry by double-clicking it. Say “yes”..

We have now imported those settings successful into our Registry (You need to have administrator rights for doing that)

Torrentzip is now ready for using.

! If you are using a 32-bit Windows. Do the same but change the exe name in the reg-file to match your executable.

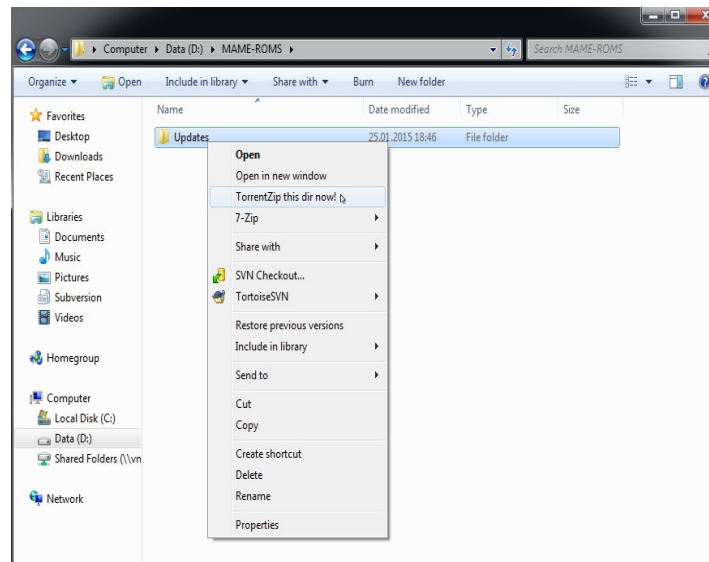

Using torrentzip

We have now “installed” torrentzip and it is available in the context menu.

We want to test if it does work. Go to a ROM-folder and do a right-click and choose “Torrentzip this dir now”

! Test it first with a test-folder and not with your only full ROM folder !!

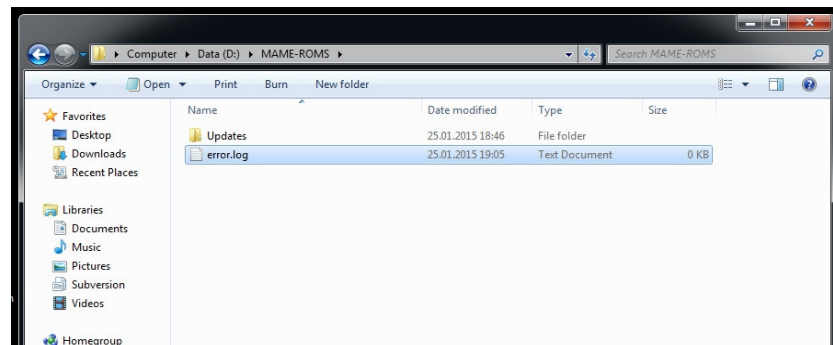

It will start a command-line windows with torrentzip all the files.

When it has finished it has created an error.log

In our case it is empty because everything went smooth. If there are errors like “read-only” or corrupt zip-files it will save this information into this file.

For the first time we want to verify with torrentzip that it has done his work. We start a cmd-windows and change to the torrentfolder and add the following command “trrntzip64.exe d:\MAME-ROMS\Updates\”

We see that everything is correct, no errors, good. We can now use it for all ROMs-folder that we want to update with a torrent. Be sure that you don't forget to torrentzipping it first before joining. I have set my torrent-client to not start the torrent after I have added a torrent. So you have the change to verify it first and see if you could start it or not at a high percentage.

Torrentzip creates btw log-file in your d:\tools\ folder → delete them from time to time.

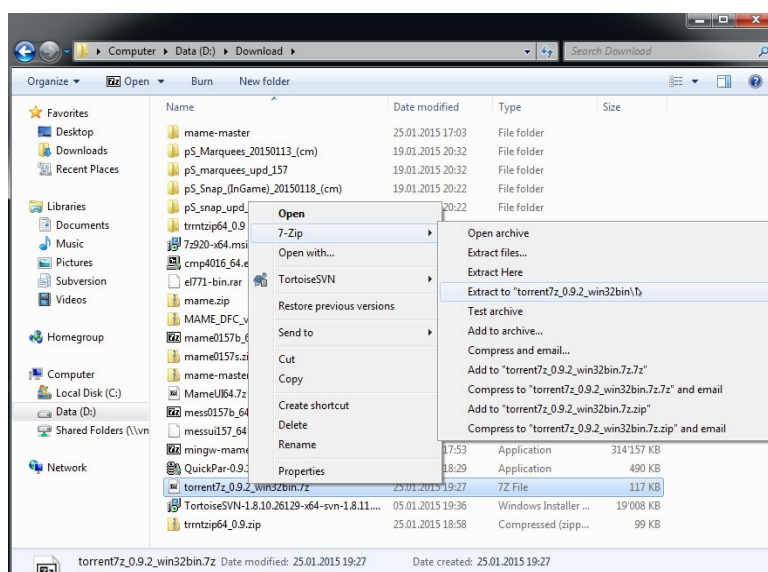

Installing torrent7zip

If you want/have to store your ROMs-zip with 7zip compressed you must use the torrentzip for 7zip ;-)

Download it from here: <http://sourceforge.net/projects/t7z/>

Download the 32-bit version as no 64-bit is available. Extract the downloaded file into a folder.

Move all extracted files

..to a folder called “torrent7zip” in your tools folder (create it first)

Create a “register_torrent7zip.txt” file in that folder.

Open it with notepad and add those line into it:

```
REGEDIT4
```

```
[HKEY_CLASSES_ROOT\Directory\shell\Torrent7Zip]
```

```
@="Torrent7&Zip this dir now!"
```

```
[HKEY_CLASSES_ROOT\Directory\shell\Torrent7Zip\command]
```

```
@="D:\Tools\torrent7zip\t7z.exe -y \"%1\""
```

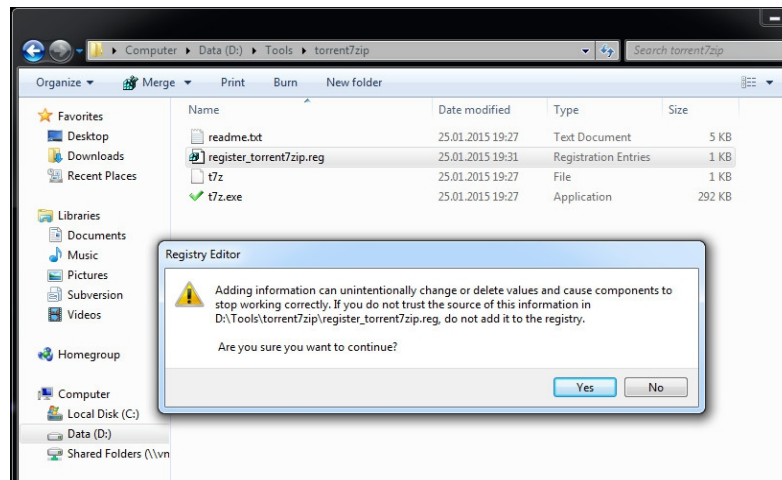

Save it and rename it to “register_torrent7zip.reg”

Import that settings into the registry → double-click it and say "yes"

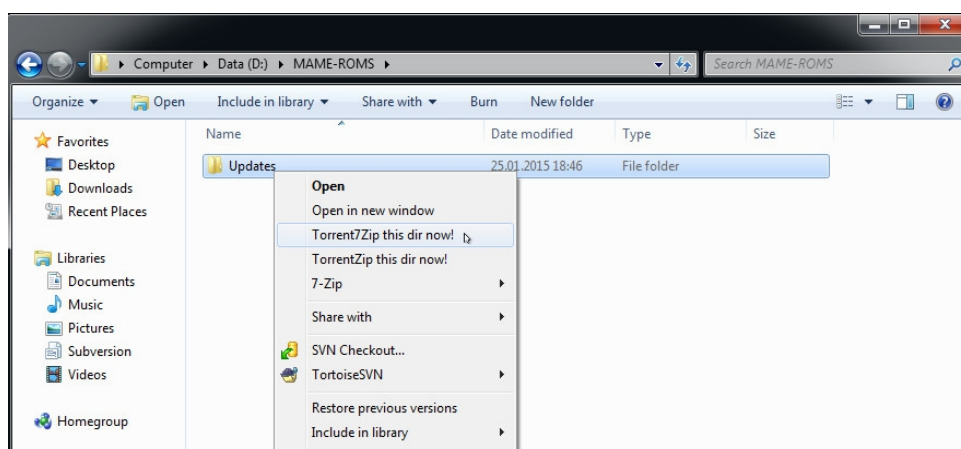

We are now ready to use it.

Using torrent7zip

We want to use that on a folder that has 7zip-files !

**! Be sure that you choose a folder with 7-zip files and NOT zip-files.
! Otherwise all zip-files will be converted to 7zip-files !!**

Right-click a folder that you want to torrent7zipping (test it first on a test folder!)

It starts to do it jobs (yeah I know in my example I am converting zip-files into torrent7zipped 7zip-files :-))

After it has finished we can test it manually with the command-line tool.

Everything is okay we are now ready to join a torrent.

Chapter 6: ROM-Tools

In this Chapter I am describing which ROM-tools I am using and how to handle it. There are a lot of other useful tools available that I have never or used in the past.

Dat-file XML-Structure

Let's have a look at a DAT-File. It has changed in the past to a XML-Structure. With MAME we can export the list into a XML-file with the following command:

```
D:\Mame>mame64.exe -listxml >name-0158.xml
D:\Mame>
```

We have now our first XML-File containing the information of all games. Open the file with notepad:

```
mame-0158.xml - Notepad
File Edit Format View Help
<?xml version="1.0"?>
<!DOCTYPE mame [
<ELEMENT mame (game+)>
  <!-- game build -->
  <!-- game debug -->
  <!-- game name -->
  <!-- game nameconfig -->
  <!-- game description, year?, manufacturer?, bioset?, rom?, disk?, device_ref?, sample?, chip?, display?, sound? -->
  <!-- game name -->
  <!-- game sourcefile -->
  <!-- game isbios -->
  <!-- game isdevice -->
  <!-- game ismechanical -->
  <!-- game runnable -->
  <!-- game cloneof -->
  <!-- game romof -->
  <!-- game sampleof -->
  <!-- game description -->
  <!-- game year -->
  <!-- game manufacturer -->
  <!-- bioset -->
  <!-- bioset name -->
  <!-- bioset description -->
  <!-- bioset default -->
  <!-- rom -->
  <!-- rom name -->
  <!-- rom bios -->
  <!-- rom size -->
  <!-- rom crc -->
  <!-- rom sha1 -->
  <!-- rom merge -->
  <!-- rom region -->
  <!-- rom offset -->
  <!-- rom status -->
  <!-- rom optional -->
  <!-- disk -->
  <!-- disk name -->
  <!-- disk sha1 -->
  <!-- disk merge -->
  <!-- disk region -->
  <!-- disk index -->
  <!-- disk writable -->
  <!-- disk status -->
  <!-- disk optional -->
  <!-- device_ref -->
  <!-- device_ref name -->
  <!-- sample -->
  <!-- sample name -->
  <!-- chip -->
  <!-- chip name -->
  <!-- chip tag -->
  <!-- chip type -->
```

There are a lot of information inside this file. We are now using a “cutted down” version for showing you how it is built.

```
mame-0158-example.xml - Notepad
File Edit Format View Help

    <device_ref name="sega005_sound"/>
```

A set of opening and closing tags and the information in-between is called an element. The text below shows a complete element:

```
<description>005</description>
```

A tag is characterized by text surrounded by less than and greater than symbols: <tag>. Each tag must have a closing tag: </tag>. All text between the closing and opening tags belongs to the tag.

If there is no content between the tags we can combine opening and closing tag into one self-closing tag: <tag/>. This is done when either there is no content, or when the content of a tag is given as an attribute of the tag, for

example::

```
<description description ="005"/>
```

is equivalent to

```
<description>005</description>
```

In our next picture I have coloured some of the tags. There is always a beginning tag <name> and an end tag </name>. For example everything between <mame> and </mame> are information about all available games in MAME. Between <game> and </game> are information for one game (for example 005). Now you can hopefully read the structure. When an ending tag is missing → the XML is invalid!

```

ROM-Manager does only read that elements that has ROM information in it or samples and uses that for verify that a ROM is valid. If you look at a created DAT-file from DFC (see next chapter) it has only the ROMs information inside (More or less) ;-)

It has the same structure beginning tag <tag> and ending tags </tag>

The block “header” has information about the DAT-File. ROM-Manager are using that tags for displaying it within the program.

DFC- Dat-File-Creator by ARMAX

With this tiny little tool we can create easily MAME/MESS DAT-files. This tool was created by ARMAX as a request by Newuzer. It can create also real diff-DAT-files from two MAME executable. What does it mean “real”? It compares two DAT-files and creates a new diff-file containing only the difference. It lists missing ROMs only once depending on their hash-code. Sets created with a ROM-Manager and this diff-DAT-file can not be used for gaming. It needs another step creating the full-set with a ROM-folder and a folder that contains this diff-ROM-files.

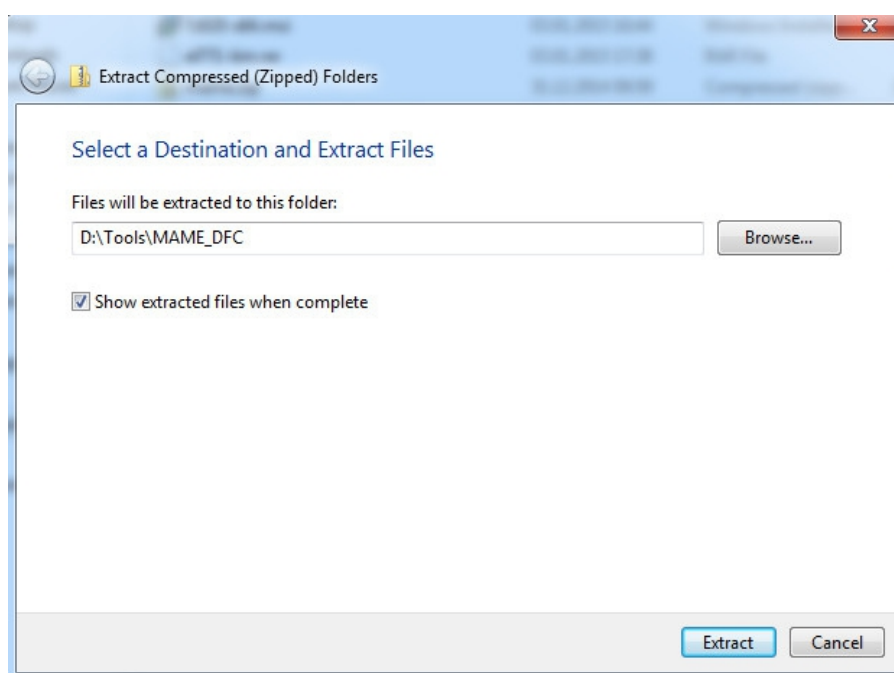

Installing Dat-File-Creator DFC

Download the program from mameguide.info to the download folder.

This program (Zip-File) has no installer. We extract it to our tools folder on the data-drive in a folder called “MAME_DFC”

We have now the executable in this folder

! Extract this tool not to the default “Program Files” folder when you have UAC enabled. This program writes the setting to a XML-file where the exe is. Otherwise you must start it as an administrator!

Using Dat-File-Creator DFC

Let's create first a shortcut on the Desktop. We drag-and-drop the executable with a right-click to the Desktop. We choose “Create shortcuts here” from the context menu.

We have now a shortcut on the Desktop for starting the program.

Start the program...

Here is short overview of the program:

- ① Executable to hash values (old build). This is only needed when you want to create a diff-DAT-file. It has a history drop-down list.
- ② Executable to read values (new build). This field is required! It has a history drop-down list.
- ③ Process data and defines what kind of DAT you want to create. This field is valid for the executable set in ②
- ④ Status text info of the current process
- ⑤ Browse for the executable ① to hash values

- ⑥ Browse for the executable for ② to read values
- ⑦ Process data and defines what kind of DAT you want to create for a diff-DAT-file. This field is valid for the executable set in ① and ②
- ⑧ Status progress bar info of current process. By right-click it enables us to save information.
- ⑨ Run the process → creates the chosen DAT-files
- ⑩ Stop the running process

That's a short explanation of the functions. We will see how does it work when we use it in our examples.

Create a DAT-file with DFC

We are now using DFC to create DAT-files that we can use later in a ROM-Manager for checking a ROM-folder.

We choose the MAME 0.157 executable and browser for it with the “read” button:

Be sure that you list the executable in this read-field (mandatory) and not in the field above.

Now we have to define what data should be process that creates the DAT-files:

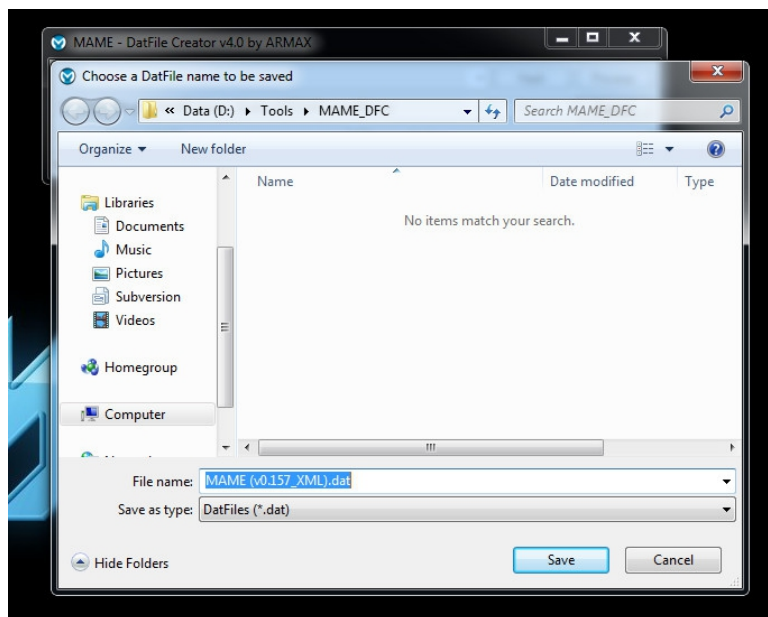

There are 5 options available:

- Process Nothing: Nothing will be process → nothing happens !
- Process ROMs: It creates a DAT-file that has only ROM-information
- Process CHDs: It creates a DAT-file that has only CHD-information
- Process ROMs + CHDs: It creates two DAT-files, one for the ROM-information and the other for the CHD-information
- Process ROMs & CHDs: It creates one DAT-file that have the ROM and CHD information included

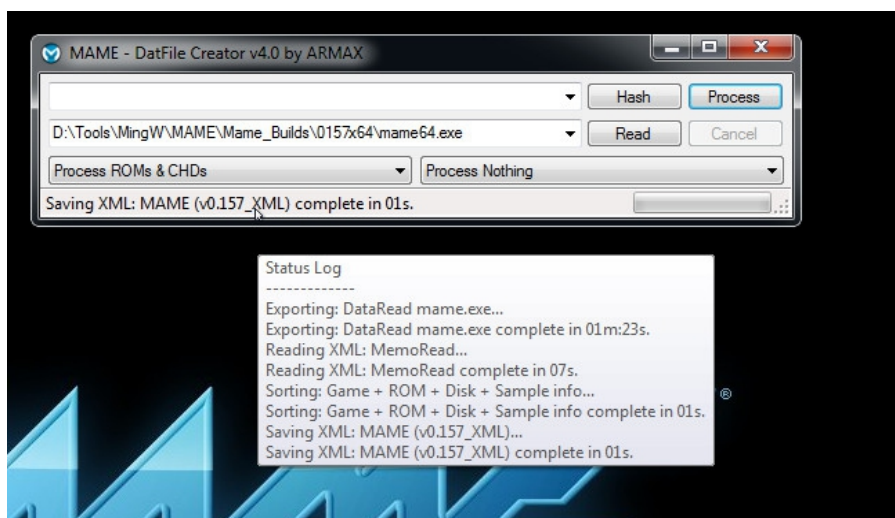

We choose “Process ROMs & CHDs” and click “Process” to start it.

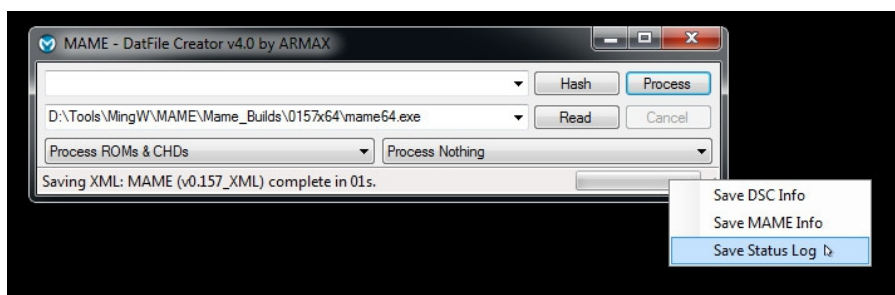

After a while it ask us for the name and where it should save the ROM-DAT-file. We save this file to the MAME_DFC folder with the name that is proposed.

The process has completed and we can point our mouse to the status bar and it displays the status log of this finished process.

We can save this log by right-click in the status area (if needed).

We have now a DAT-file in the program folder that contains ROM and CHD information.

! After you have used the program for the first time it creates a XLM-file in the program folder that contains the settings and the history.

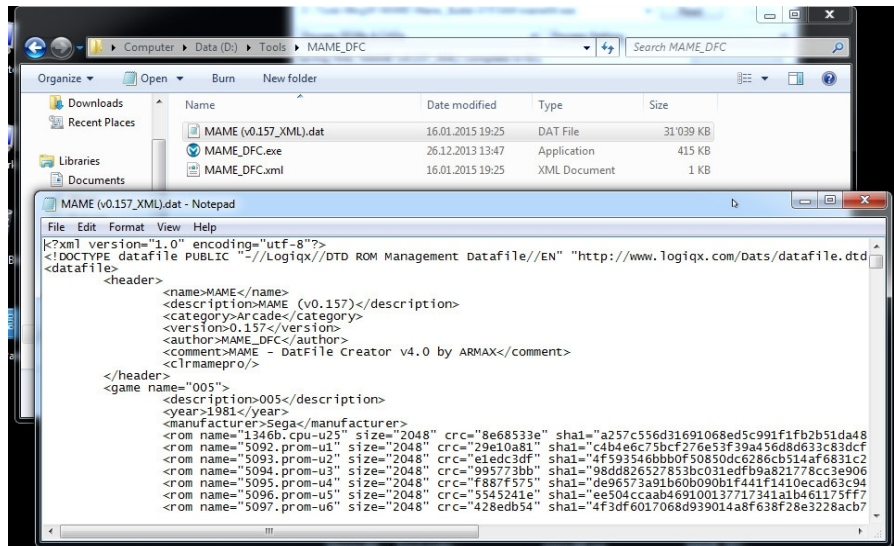

We open the created DAT-file and see what the content is.

Double-click the file and choose Notepad for opening.

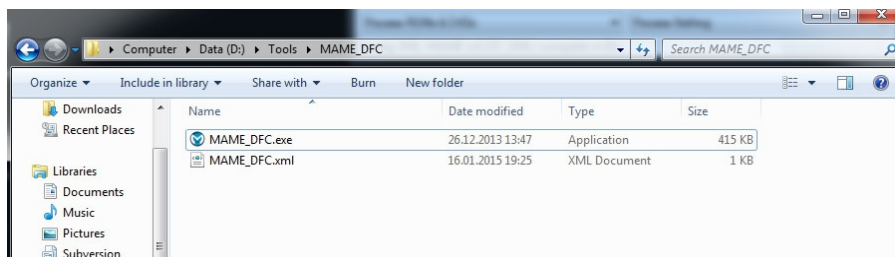

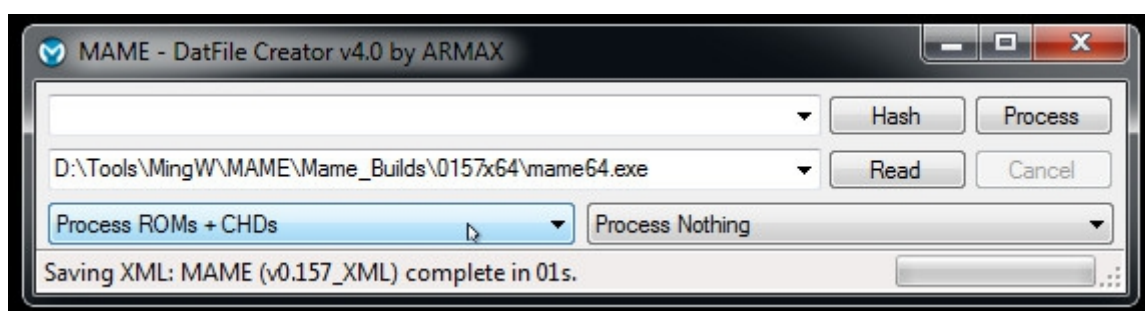

The created DAT-file looks like this:

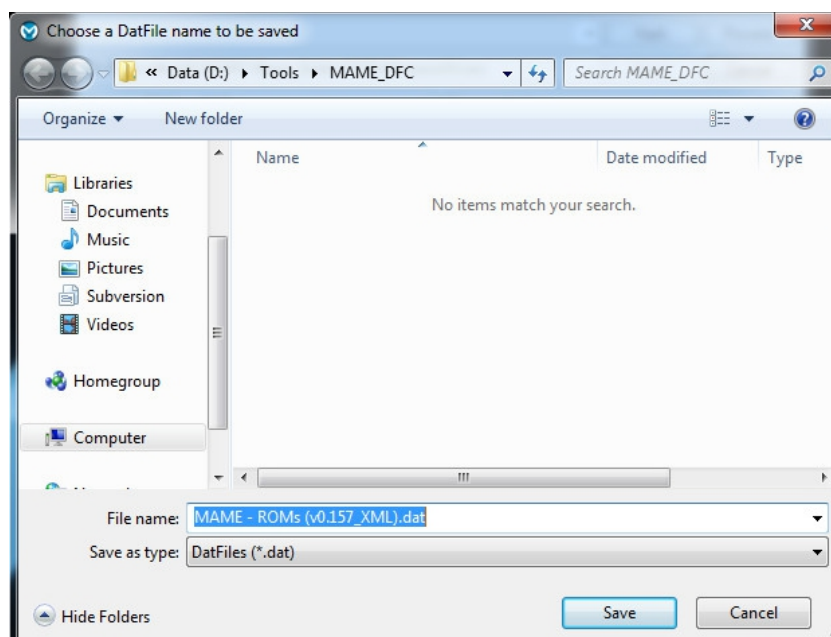

Okay close Notepad and delete the created DAT-file. We want to create again DAT-files but this time two separate, one for the ROM and one for the CHD information.

Let's go back to DFC and choose now “Process ROMs + CHDs”. Click “Process” to start it.

Again after it has read the values from the executable it will save the ROM-information. Choose again the DFC program folder for saving and let the name untouched.

After you have save the ROM-file it will ask again for the saving information for the CHD-DAT-file. Choose the DFC program folder and leave the file name unchanged, save it.

! If you have chosen “Process ROMs + CHDs” and the executable has no CHD-information the safe dialogue is appearing for the CHD-DAT-file but it will not save a CHD-DAT-file.

We now have two DAT-files in our DFC program folder that we can use for verifying a set with a ROM-Manager.

Name	Date n
MAME - CHDs (v0.157_XML).dat	16.01.2
MAME - ROMs (v0.157_XML).dat	16.01.2
MAME_DFC.exe	26.12.2
MAME_DFC.xml	16.01.2

Create a diff-file with DFC

We are now creating diff-DAT-files from the official MAME 0.157 executable and MAME that we have created with a later release ourself (see Chapter Compiling).

! Keep in mind that this function was not intended for “normal” users. It is used for people who collect ROMs and share them to others.

We start DFC and set the hash-field to the official 0.157 MAME executable

Now we choose and set the Read-field to one of our own compiled builds (be sure that the release number is higher than the official 0.157 build!)

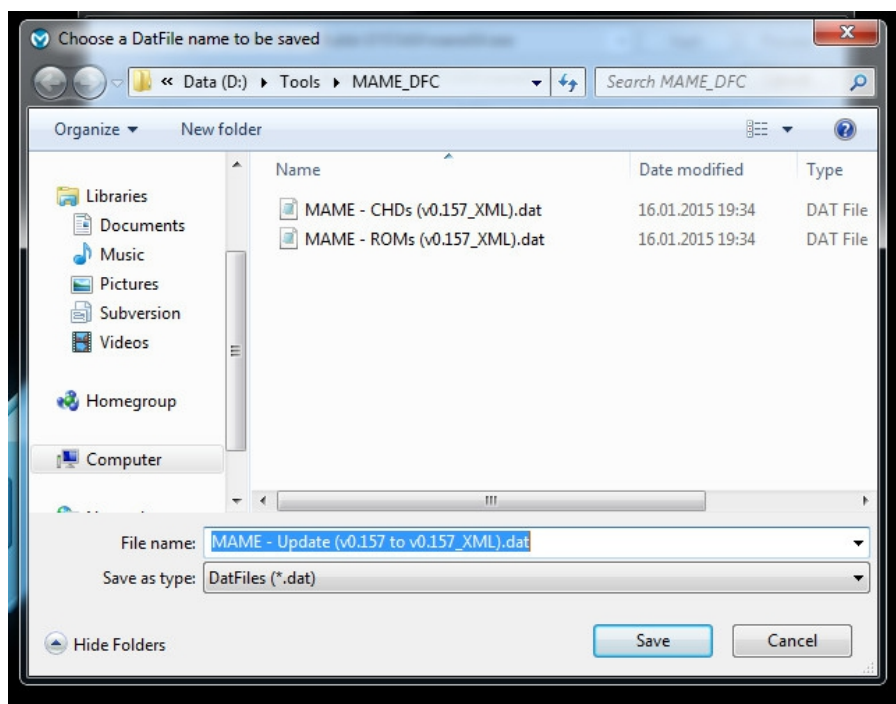

We set “Process nothing” in the left “processing bar” and on the right we set it to “Process Update ROMS & Update CHDs” as we want one update DAT-file with CHD and ROM-information to be created. The right “Process bar” has the same opportunity as the left one described a little earlier in this section.

Let's start the process

Save the file again to the DFC program folder

It saves the file to the folder and finishes the process.

I'm renaming the file to the release number (from to version) for identify it better.

We open the created DAT-file with Notepad and change there also in the description the number to the release number.

We have now created a DAT-file that has only the difference between two executable (MAME/MESS) and includes ROMs and CHDs information.

Additional functions DFC provide

When we have set in the read-field an executable we can right-click the progress bar and choose “Save DSC Info” from the context menu. This function has ARMAX build in only for Retroroms.net requested by me. The saved file is being used on the web server for displaying the game name of a zip-file.

When you open the file it looks like that:

Retro- ROMs			
CHD update in progress - Please do not download CHD's until further notice			
Name	Last modified	Size	Description
Parent Directory			
005.zip	26-Jan-2013 05:18	29K	005
1on1gov.zip	26-Jan-2013 04:48	14M	1 on 1 Government (Japan)
2mindrll.zip	26-Jan-2013 05:20	5.2M	Two Minute Drill
3bagflnz.zip	26-Jan-2013 14:29	25K	3 Bags Full (3VXFC5345, New Zealand)
3bagflvt.zip	26-Jan-2013 15:24	51K	3 Bags Full (5VXFC790, Victoria)
3countb.zip	26-Jan-2013 02:36	7.3M	3 Count Bout / Fire Suplex (NGM-043)(NGH-043)
3dobios.zip	26-Jan-2013 01:37	2.2M	3DO Bios
3in1semi.zip	26-Jan-2013 14:17	1.1M	XESS - The New Revolution (SemiCom 3-in-1)

The second option in the context menu when you right-click the progress bar is “Save MAME Info”.

This information requires that you have chosen an executable in the read-field and hash-field.

The saved txt-file contains information about the difference between those two executable. And it displays also the removed, added or changed ROM set by name. I have used this information for creating the MAMEtitles in the past. This function has ARMAX programmed for me only :-)

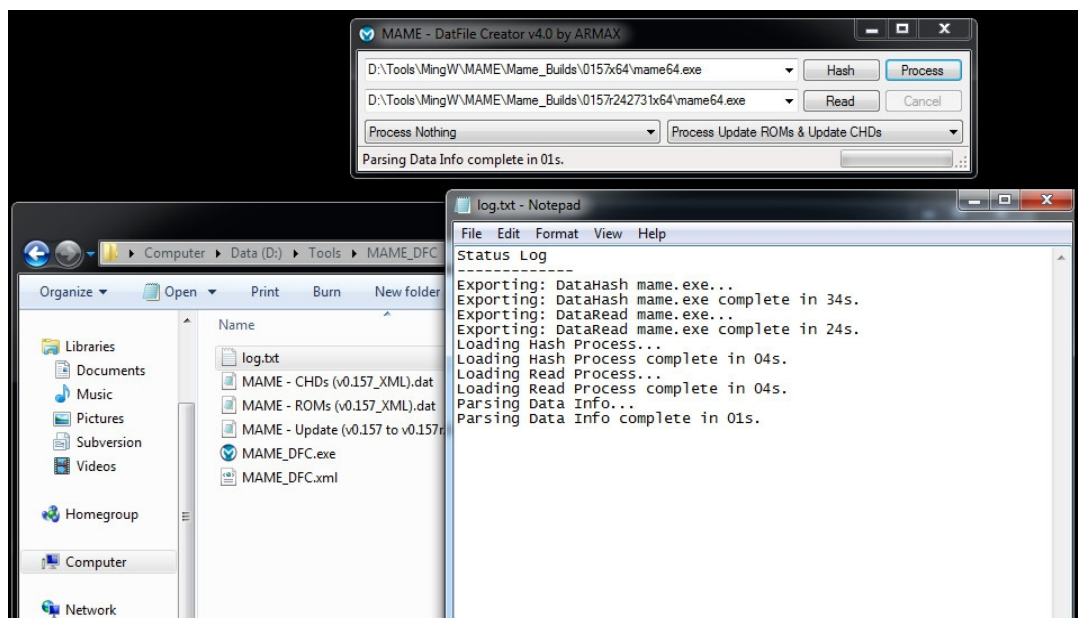

The third option in the context menu is saving the status of the process to a file.

The saved txt-file opened with Notepad.

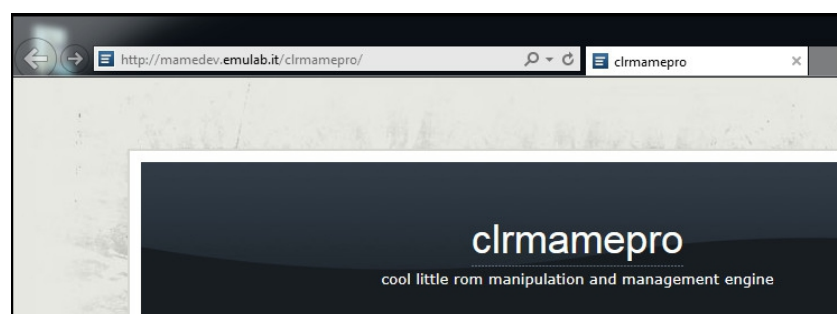

CLRMAME - Cool little ROM manipulation and management engine by Roman Scherzer

One of the powerful ROM-Manager tools that is available is CLRMAMEPRO. It is a tool that helps you organize your ROMs in a perfect way. You can scan, rename, delete and rebuild your ROMs with this tool easily. MAME/MESS has nothing build-in for organizing the ROMS, it does only complain when a ROM is wrong or missing. With CLRMAMEPRO and a DAT-File you can create and update your ROM-set easily. I will show you how we can do this and not only for ROMs, we are also scanning other files like snapshots with this amazing tool and keep them updated.

Installing CLRMAME

We are starting a web-browser and open the CLRMAMEPRO homepage.

On the left choose “clrmamepro download”

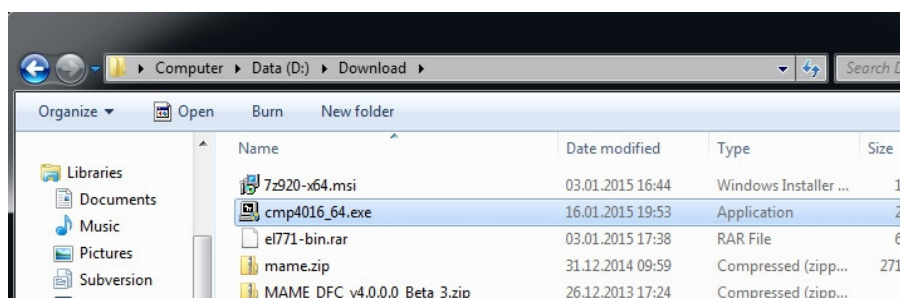

There are two available version there, a zip-file and an exe that has an installer. We choose the 64-bit installer version to download.

We save it to our download folder.

We start the setup ...

As our destination folder we choose the tool folder on our data-drive

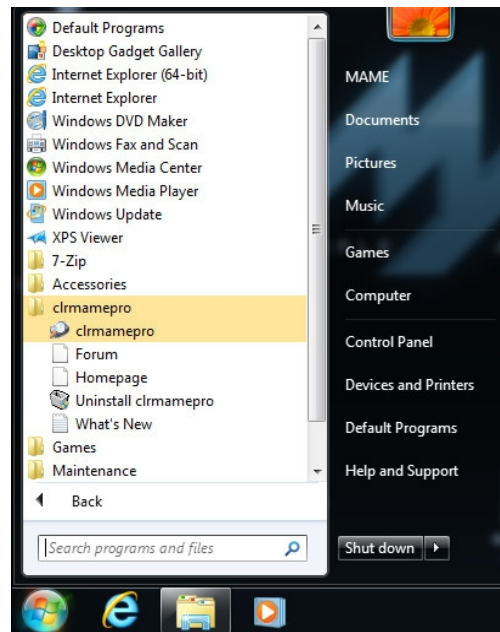

! Install CLRMAMEPRO not to the default “Program Files” folder when you have UAC enabled. This program writes the settings and logs into his folder where the exe is. Otherwise you must start it as an administrator!

Click “install”

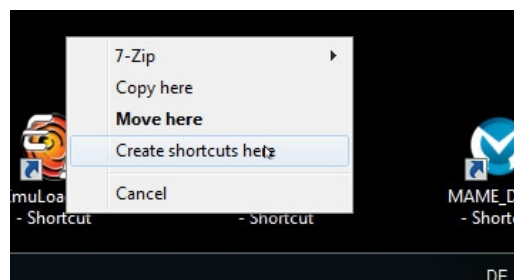

The installer has created an entry in the start menu.

We are lazy and want to have a shortcut on our desktop. Drag-and-drop the entry to the desktop and choose “Create shortcut here” from the context menu.

We have now a shortcut on our Desktop.

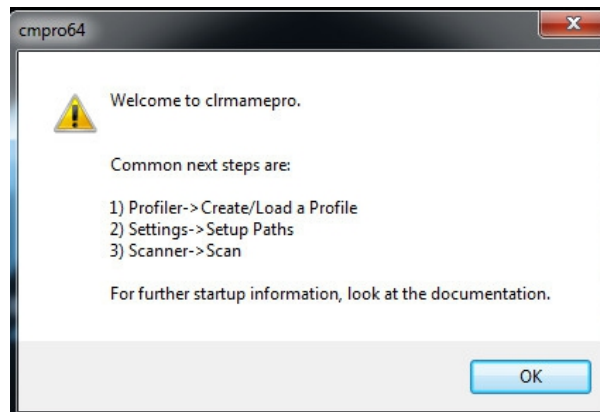

We have now installed the program. When a new version is available we can update with the build-in update function easily.

Using CLRMAMEPRO

When we start the first time CLRMAMEPRO it will show you this “welcome” message and displaying the next few steps.

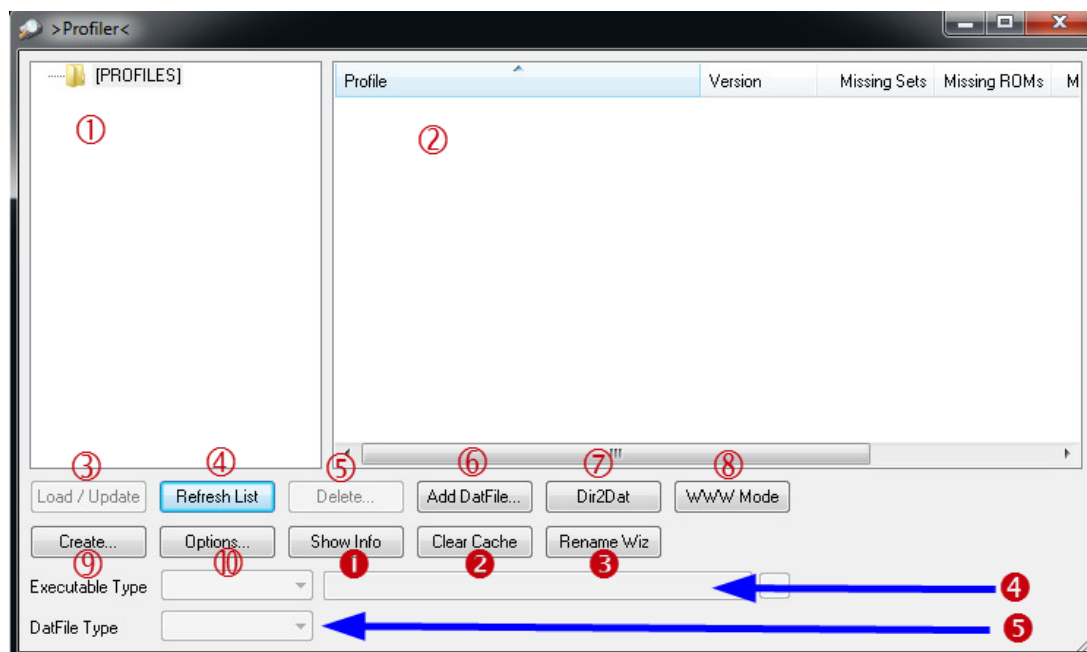

After “OK” the profiler is starting. This profiler is the start for every function CLRMAMEPRO does provide. With this we choose and load a DAT-file and do all next steps. We can scan, rebuild or merge the set with the loaded DAT. If we want to scan another set we have to go back to this profiler and load the wanted DAT-file into CLRMAMEPRO. It sounds very complicated but it isn't. I will show you how does it work.

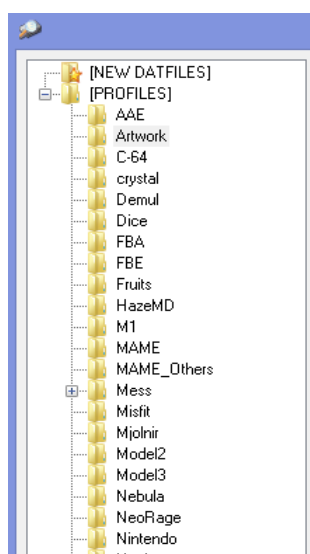

Default Settings (overview)

Let's describe all functions and buttons. We will learn how to use it later.

This is the profiler window.

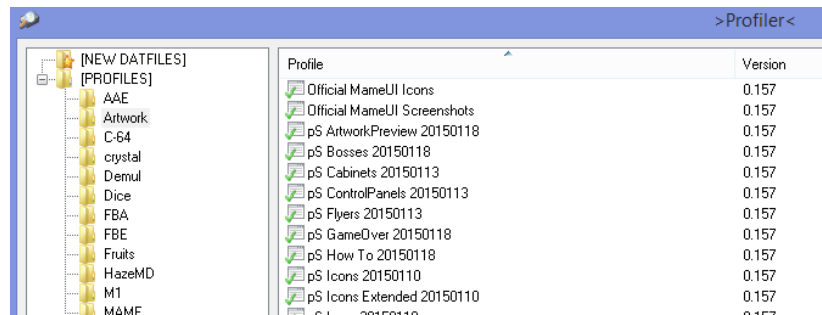

① In this section you see the profiler folder structure

- ② There you see all added DAT-File in the chosen folder structure

- ③ Loads/update a chosen DAT-File
- ④ Refresh the view → Scans for new DAT files in the folder structure
- ⑤ Deletes the DAT-file you have chosen

- ⑥ Adds a DAT-File using the file explorer

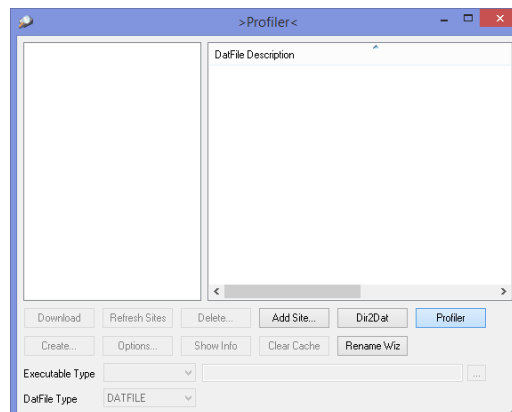

- ⑦ Dir2Dat → Creates a new DAT file based on a folder structure

- ⑧ WWW Mode → Settings for updating added DAT-Files by the WWW

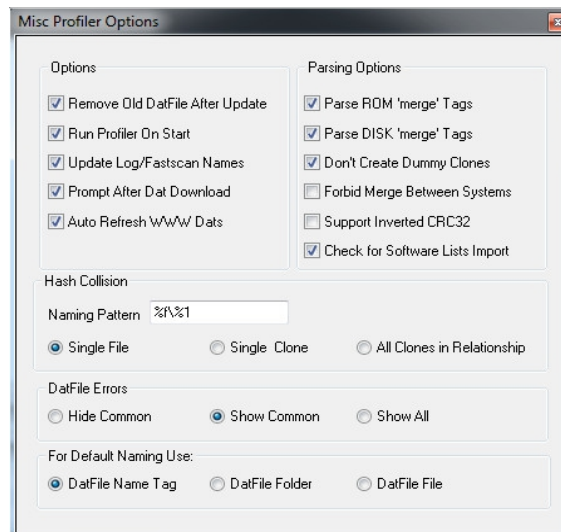

- ⑨ Create a DAT-File with an executable

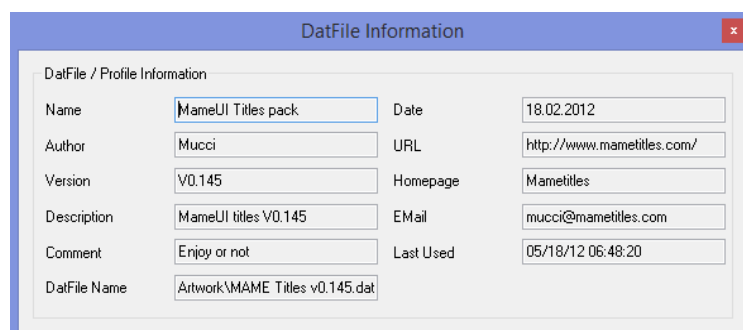

⑩ Profiler options

❶ Show info - displays information about a DAT-File

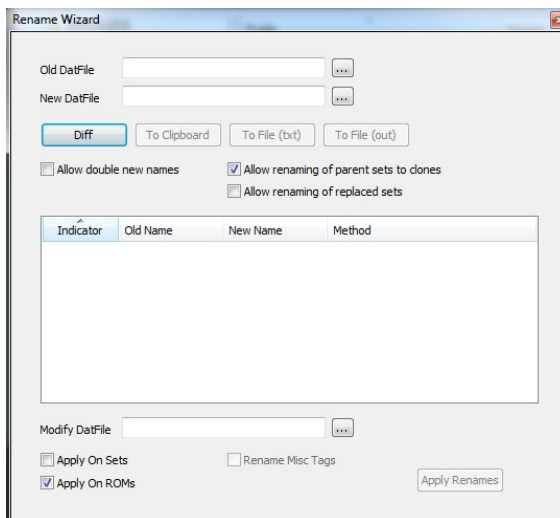

❷ Clear Cache → clears the cache of a chosen DAT-File

③ Rename Wizard

④ When you have created a DAT-File with an executable it shows you the type and which EXE is used

⑤ Display the type of the chosen DAT-file

! Every button/field in the program displays additional information when you move your mouse pointer over it.

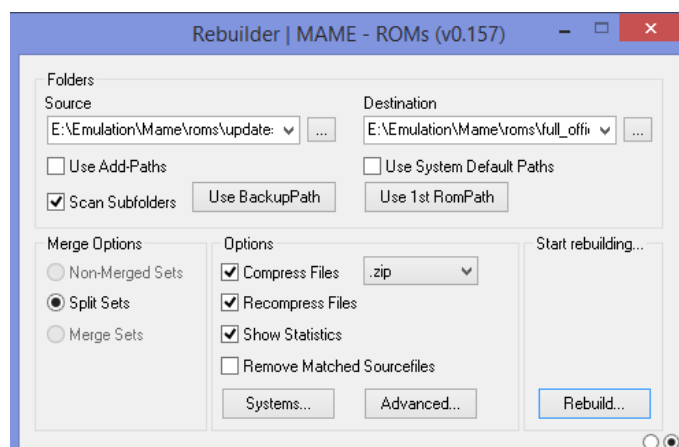

After we have loaded a DAT-File we see this main functions. Each function does its job based on the chosen DAT-File. If you want to scan a different set you must return to the profiler and choose there a new DAT-file.

① Scanner → With that you can scan your set and see if it is complete.

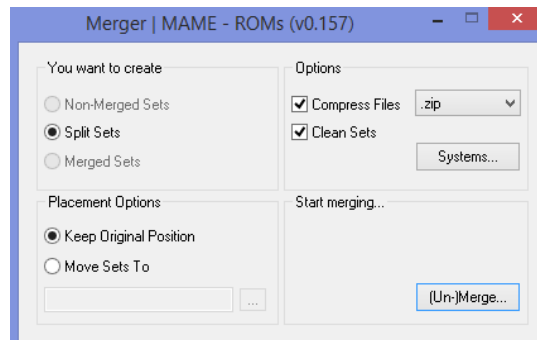

② Rebuilder → Rebuilds your set with the loaded DAT-file

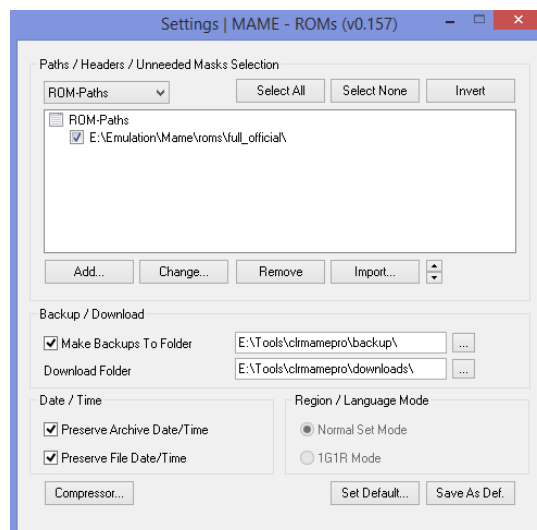

③ Merger → Change the way you have stored your ROMs (See ROM Chapter)

④ Scanner settings → Settings for the chosen DAT-File!

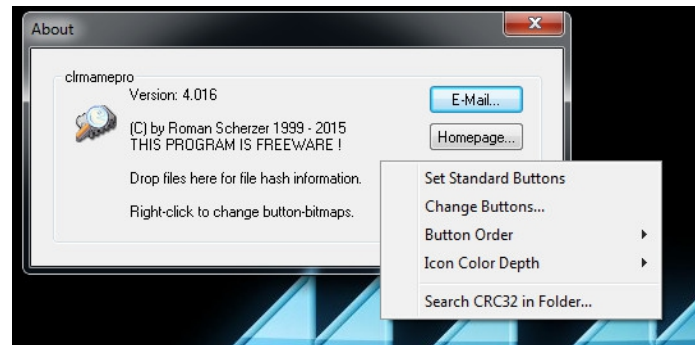

⑤ Profiler → Brings you back to the profiler

⑥ About → Information about the program/Author

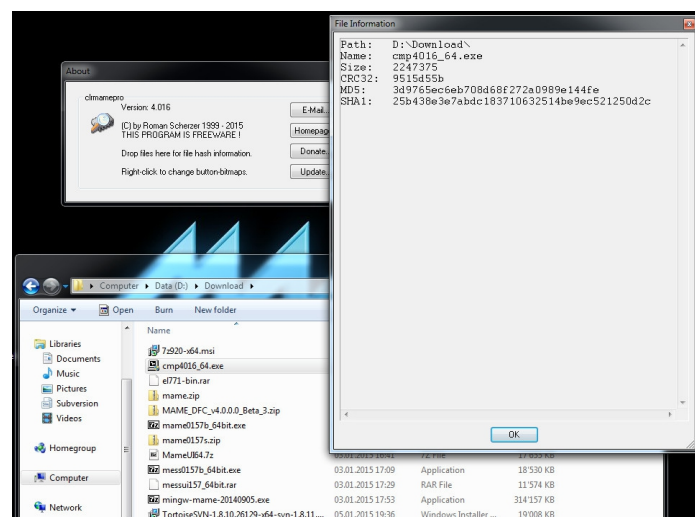

There is a “hidden” feature in this about windows. Right-click and it opens a context menu where you can change the appearance of the program.

For example → I have changed the buttons layout with a downloaded one.

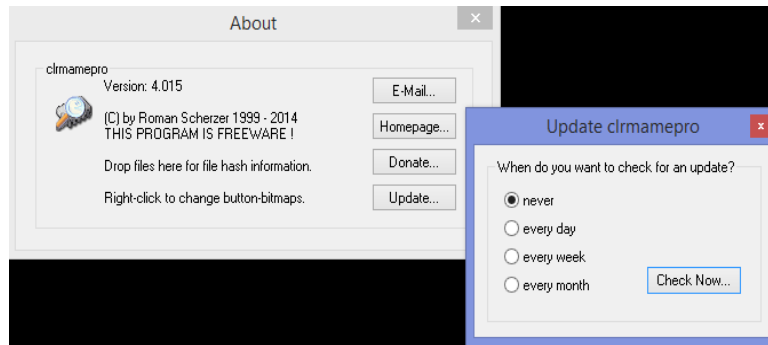

There is also a little feature that can displays you CRC32 hash information for a file.

If you want to update your CLRMAMEPRO there is a build-in update function in the about window.

That was the first look at CLRMAMEPRO. We are looking now how does it work with the following examples.

Scanning with an executable

Okay lets go back to the profile → click “Profiler”

In the profiler we choose “create”

We choose the MAME-executable from our MAME-Folder or another location where you have downloaded or compiled another build.

We write in the description field a name. This name is displayed in the profiler windows. So be aware that you choose a name that is unique.

This creator can build DAT-files for the following Emulators

We choose MAME as our Emulator type. Click “Create Profile”

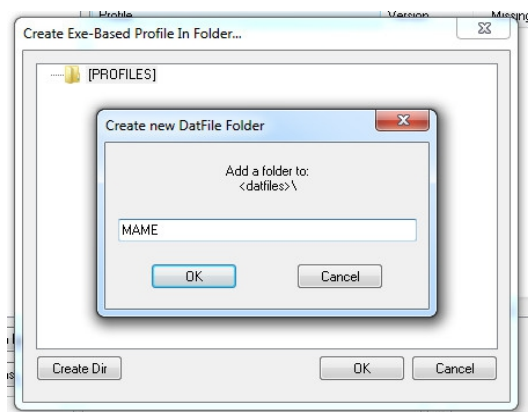

Now we must choose a folder where this created DAT-file should be stored. As we have not used CLRMAMEPRO before we create a folder first where we want to store the DAT-file.

We choose “MAME” as the folder name.

Now does it fit and we choose the new created folder and click “OK”

Now we see our first DAT-file in the profiler.

Highlight the DAT-File and click “load/update”. You could also double-click the entry.

The first time you chose a created DAT-file the program builds the information in the background. It will start the MAME executable with the parameter “-listxml”.

While this process is running you will see this window

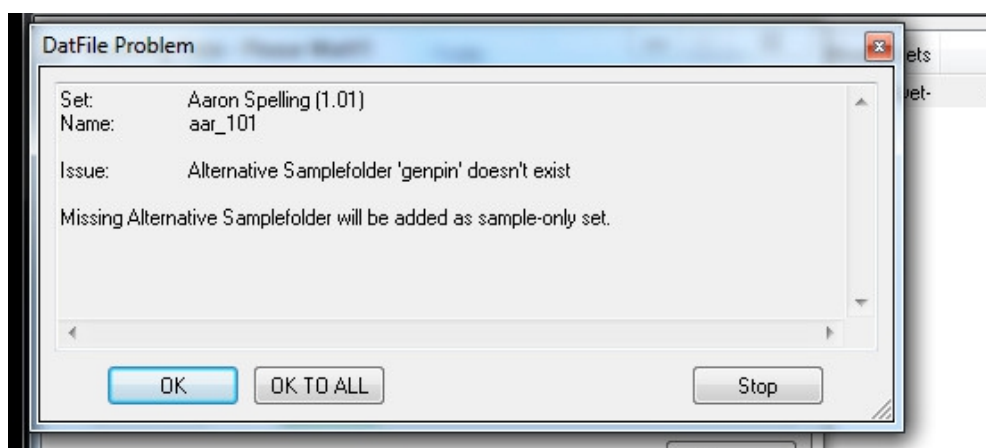

This question we answer with “no”.

! For MAME this SoftwareLists don't really make sense since MAME simply double neogeo/stv/etc roms for it. For MESS it makes sense.

When a conflict appears while creating the DAT-file it will displays the problem and you must choose what you want to do.

First conflict is about missing sample folder, choose “OK to all”. That means that on all conflict with this type “sample folder” the program will add it as a sample-only set.

Also on this question choose “OK to all”. This is more an information, you have not many possibilities to choose from ;-)

Choose “OK to All”

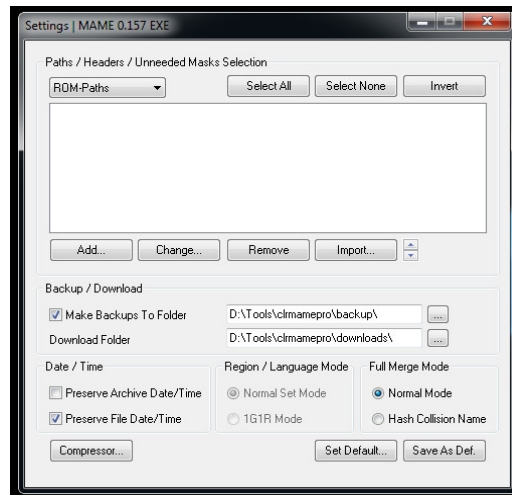

Okay the DAT-file is created and it opens the main window.

When you have loaded a DAT-File you must set the folder where you have stored your ROMs. You can do that in the “Settings”

In the drop-down list of the path you have the ability to set different path for your Set that you want to scan. If your ROMs are in two different folder, for example CHD-files are not in the same location that ROMs, you can add under ROM-Path two folder-path.

We choose ROM-Path and add the folder where our ROMs are for MAME.

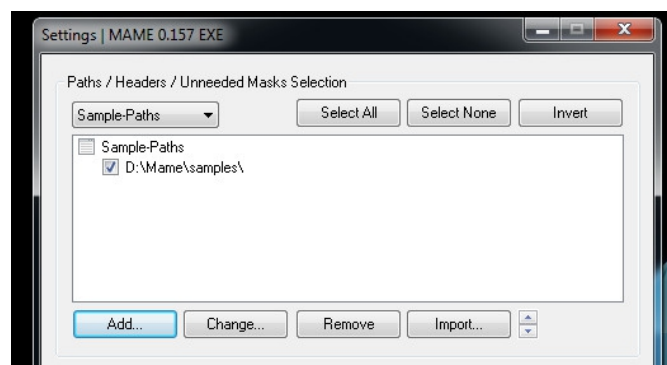

That's our ROM-Folder.

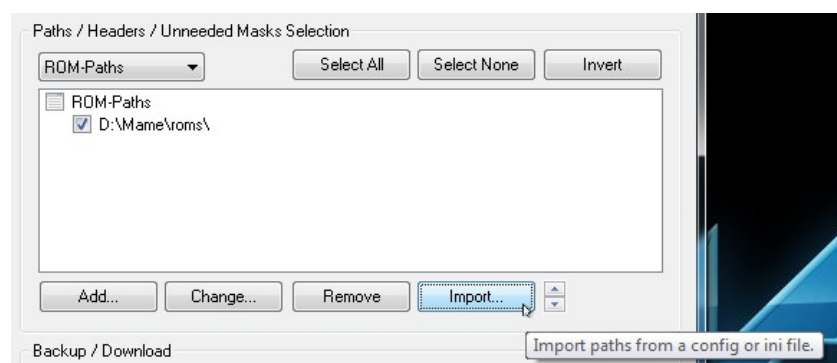

We add the path to our samples (choose Sample-Path from the drop-down)

! Have you chosen the wrong directory? We can change or remove those path if needed → Button “Remove” or “Change”

A special button is “Import”

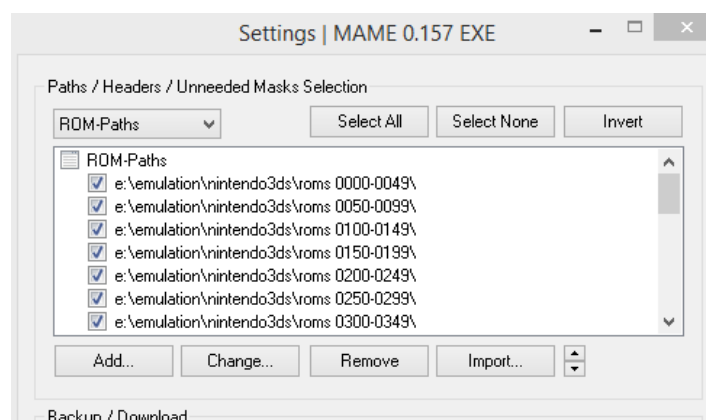

With that we can import a lot of path easy with the help of a ini-file.

The ini-file should look like that example

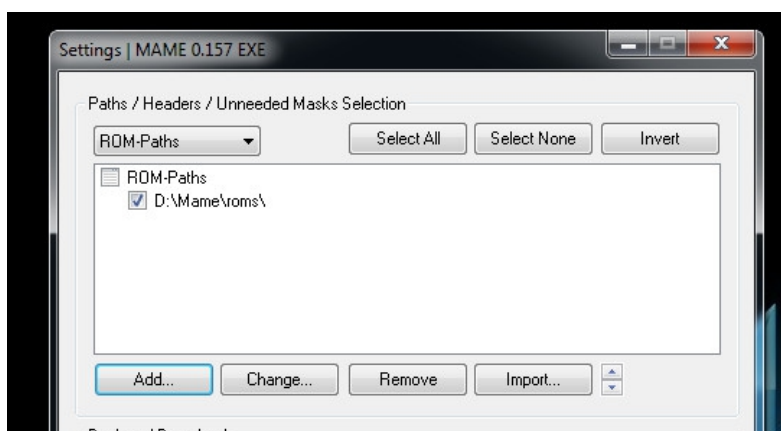

and after the import you have all the needed path

This was only an example we have only two path added and that is fine

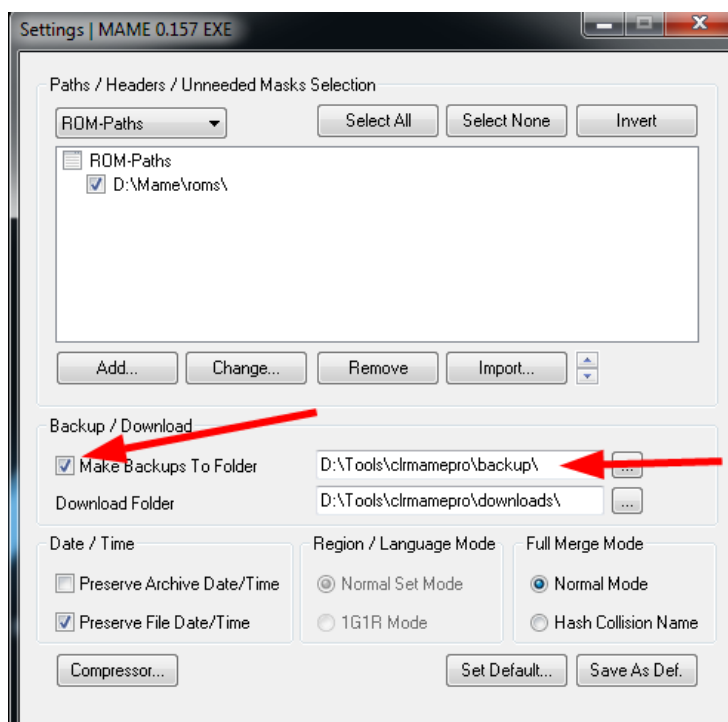

(ROMs & Samples)

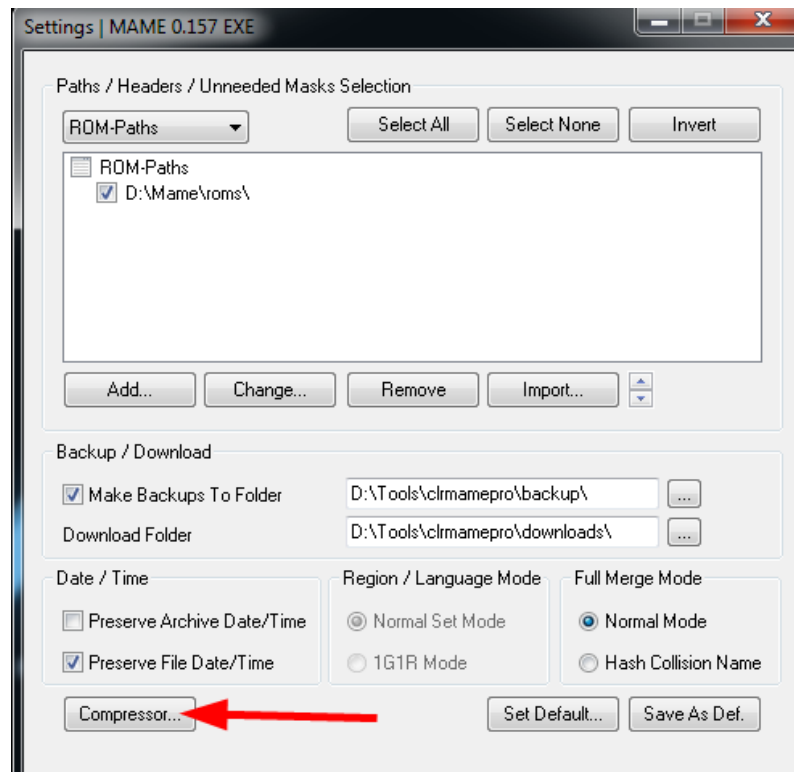

In this settings window are some other cool options we should look at.

Be sure that you enable “Make Backups To Folder” otherwise the removed ROMs during a scan are lost. I have enabled it all the time and I use that backup folder as a depot for all unknown ROMs. I put them there for a later use and with each rebuild I do I scan this folder for finding ROMs.

Click on this button “Compressor”

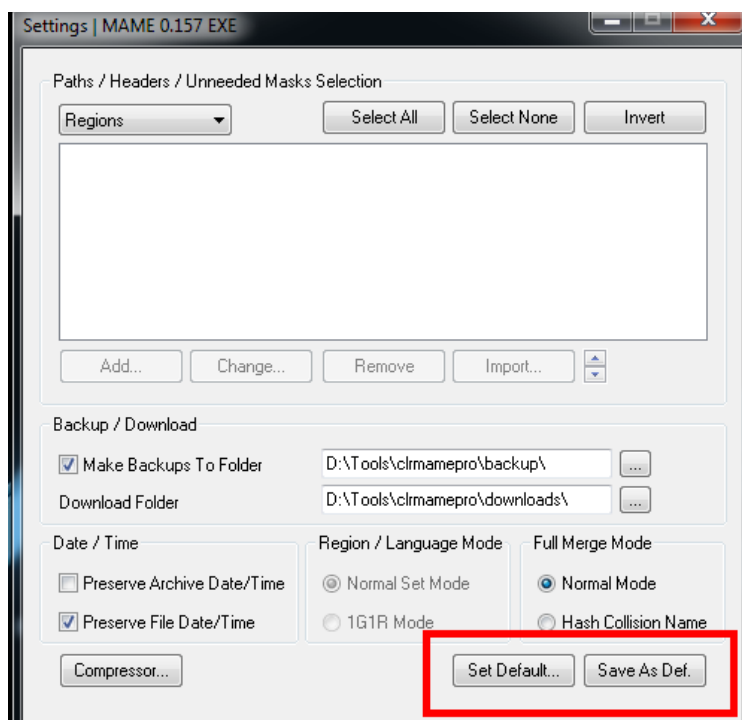

There you can set settings for 7-zip, CHDs and other settings that is used in the scan process.

We change nothing and close it with “OK”

We have at the bottom on the right side two buttons

Save as default: You can save the settings you have done as default. It is used all the time when you choose a new DAT-file in the profiler and choose “default” for the settings. Should you have created a “wrong” default saving, you can correct it or delete "default.cmp" in your CLRMAMEPRO folder and you are fine.

Set default: you can overwrite your settings and set it to the default setting again.

That's for now, we close the settings windows → press the “X” in the upper right corner of the window.

Okay everything is now set for this DAT-file and we want to do our first scan with CLRMAMEPRO. We choose “Scanner” from the main window.

Before we start let's look at some settings in the scanner window

- ① Here you can choose what you want to scan. It depends on the DAT-file you have loaded what type you can select. If in the loaded DAT-file are only ROM-information you can choose only “Sets” and “ROMs” for en-/disable.
- ② In this section you can set in detail what should be scanned and what CLRMAME should do when it finds an “error” (Fix). Be aware that when you enable something in the fix column it does change ROMs in your scanning folder when it finds something to fix!

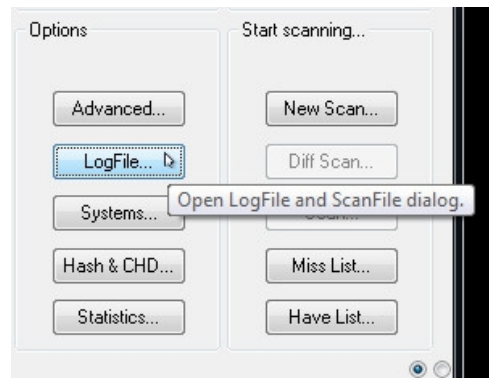

- ③ You prefer → That's how we want the ROMs to be stored (See chapter ROMS)
 - ④ Options → As the name tells us, here we can set additional settings
 - ⑤ Prompts → I have enabled that two possibilities.
 - ⑥ Start Scanning → here we can start the process.
- New Scan → When you have never done a scan with a DAT-file
 - Diff Scan → this one is only available when you have added a newer DAT-file and have chosen “upgrade” in the settings. It will takes the old information and do only a diff-scan, that means it will only scan for changed ROMs.
 - Scan → If you have already done a first scan, this process will only scan the files that has reported an error.

Let's look again the the “Options”. In the Advanced you can set additional settings.

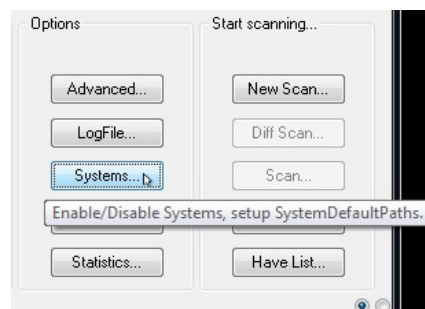

Under “LogFile”

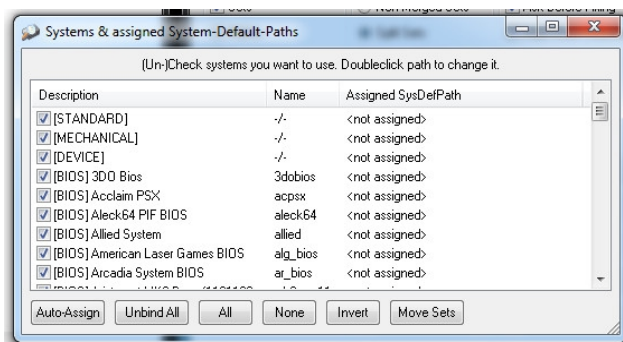

You can set the path for the Logfile and scanfile. You can change that if you need it ;-)

Under “Systems”

This entries vary depending on your loaded DAT-file. When you are loading the DAT-File with Notepad you will see ROMS that have an additional tag called “resource”. That is displayed here. Here you could do some tweaking for this, I have never used that myself.

The next entry in the Options is “Hash & CHD”

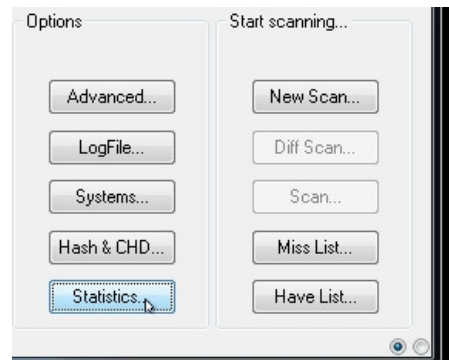

Here you can specify which checksum should be used to verify a ROM. It depends on the DAT-File what versions are available. When you create a DAT-File you can set what checksum should be generated and included in the DAT-file. We will see when we do a “Dir2Dat” later

When you choose a setting “Decompress...” it will takes much longer to scan. The setting “Decompress CHD...” will read all blocks in a CHD and does an integrity check (that could takes also a long time).

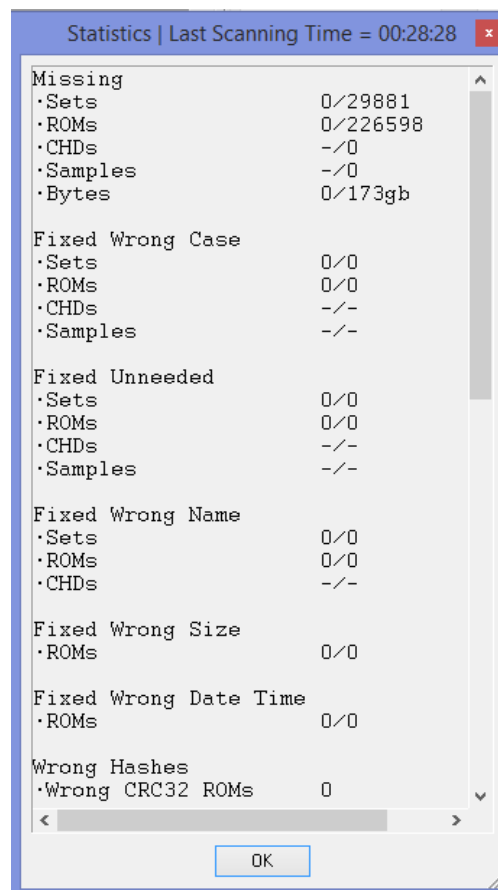

Let's go back to the Options and look at the last entry called "Statistics"

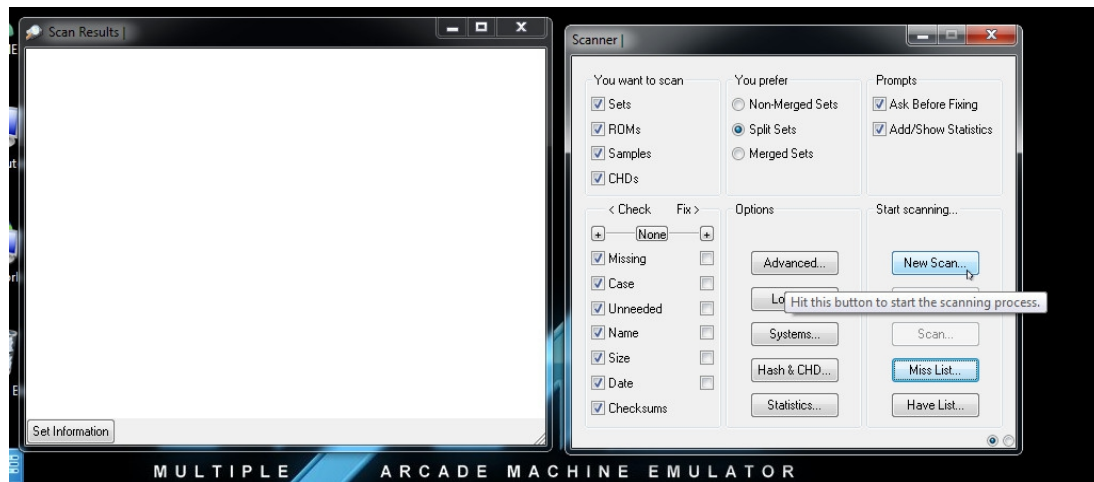

It will shows you the statistic again of the last scan.

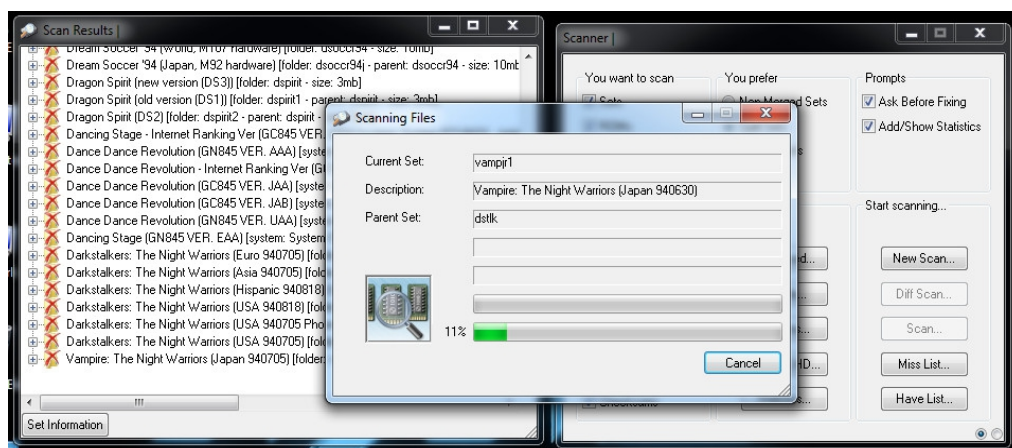

Stop talking let's do our first scan click "New scan"

We are receiving a pop-up message. It tells us that the sample path is not valid. That is okay because we have no sample zip-file stored there ...

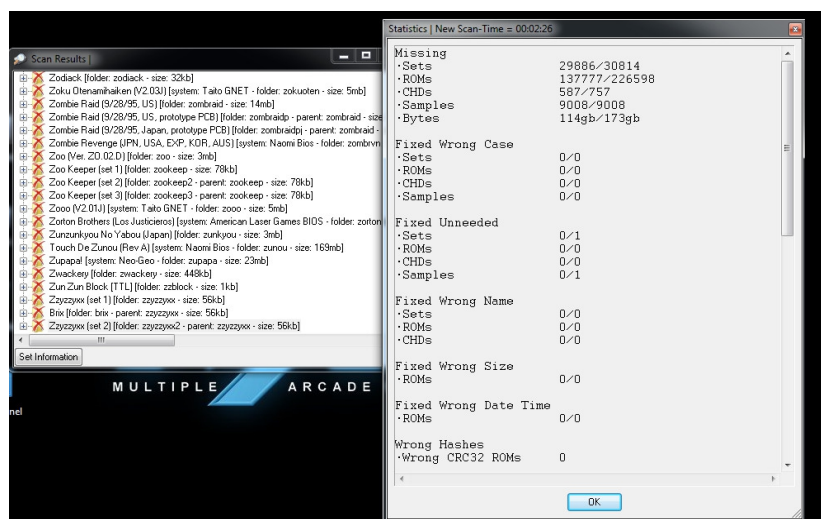

Wow it's scanning. We can see how the progress is

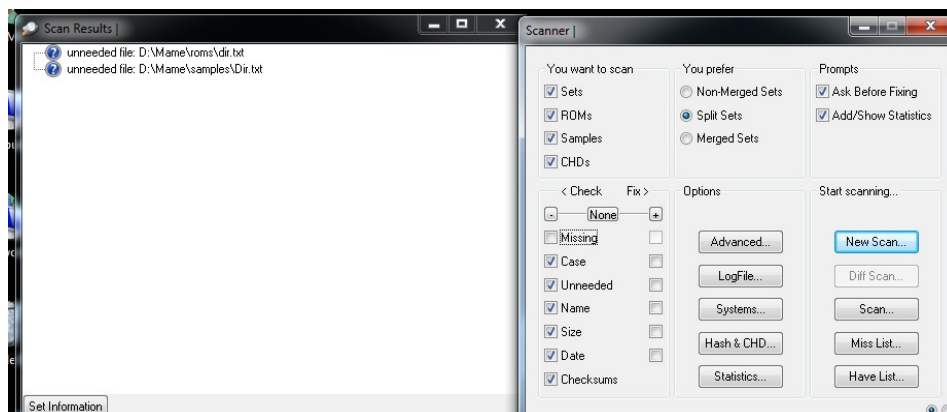

When it has finished it display a statistics window.

We have not many files in the ROM-folder (only dkong.zip) that's the reason why. We click “OK” on the statistic window. At the “Scan Results” window we see what is missing or wrong.

Can you remember what I have told you about the “Check” setting?
Uncheck “missing” and see what happens.

Those “missing” are gone and not visible anymore. Indeed we still missing those but we have changed that they should not be included in the scan.

It has only two files left in the result, they are not in the DAT-file included and that's why the are marked as “unneeded”

That was our first scan. We have verified with a DAT-file that includes information for the hole MAME set and we have only dkong.zip in our ROM-folder. We want to change that. We could do now two things:

- Download ROMs and store them in the ROM-folder. After the download we must verify/correct it with CLRMAMEPRO
- The other way is to download all ROMs to another folder and use the Rebuild-function that CLRMAMEPRO provide.

Let's choose the second way. We are seeing in other examples how we can use the scanning “fix” options to help us in creating a perfect set.

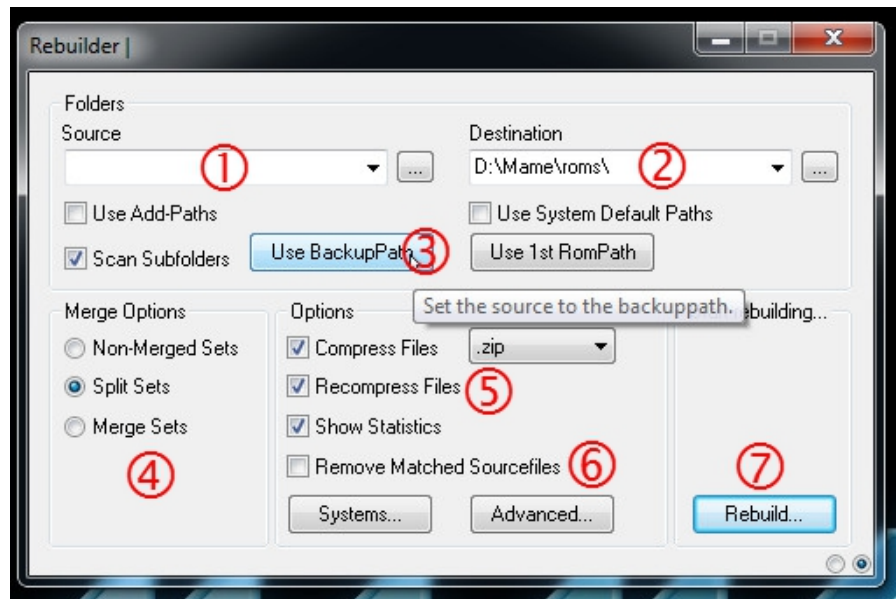

Start the “Rebuilder”

! If you have clicked “Profiler” by mistake no worry just choose again our “MAME 0157 EXE” DAT-file. It will loads all settings and everything is available again for scanning/rebuilding.

We need now all MAME ROMs to download. Get them from the internet, I think the best choice is to have a torrent as a download-source. Download and store them in a folder “Roms” in your download folder.

When we look at the Rebuilder window we see some settings. The important are:

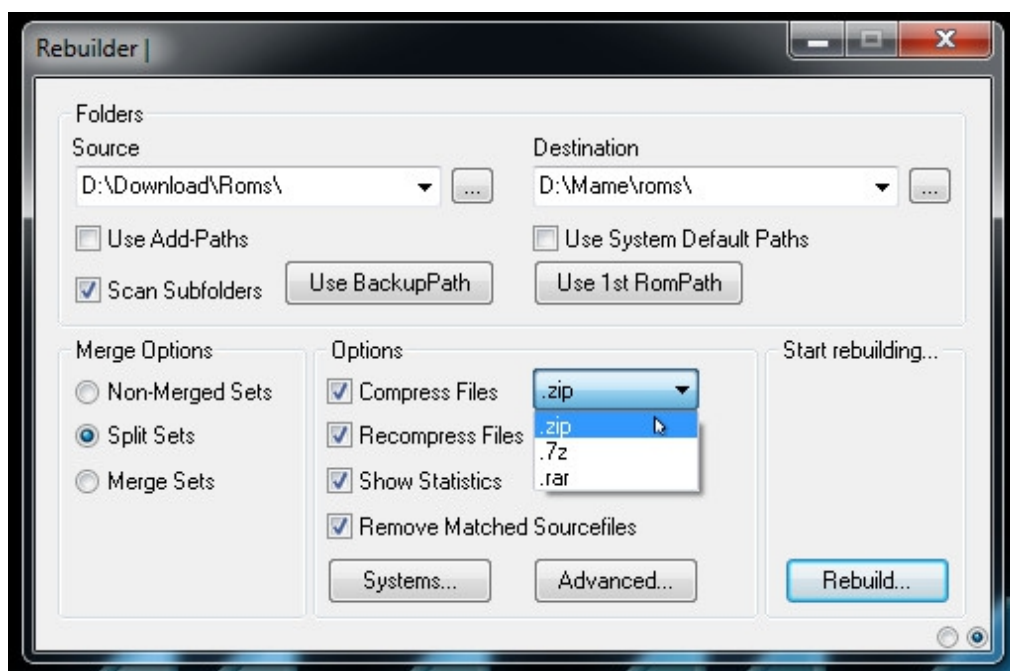

- ① Select the folder where your downloads are → from where you want to rebuild
- ② Select the destination → it points to the ROM-folder you have set in the DAT-settings. If you want to create the result not to your MAME/ROMs folder you can point it to a different location. Keep in mind that you have to move them manually to the MAME\ROMs folder after the rebuild.
- ③ “Use BackupPath” → you can rebuild also from the backup-folder that CLRMAMEPRO has. Remember I store all unused ROMs there and when I'm searching for new ROMs I do my first rebuild from this backup-folder :-)
- ④ Merge options → see Chapter ROM for more information
- ⑤ Options → some options you can set/change
- ⑥ Option “Remove matched..” → when it is enabled the matched ROMs are removed after the rebuild from the source folder.
- ⑦ Rebuild → that starts the process

We set the source folder to our Download directory and enable “Remove matched..”

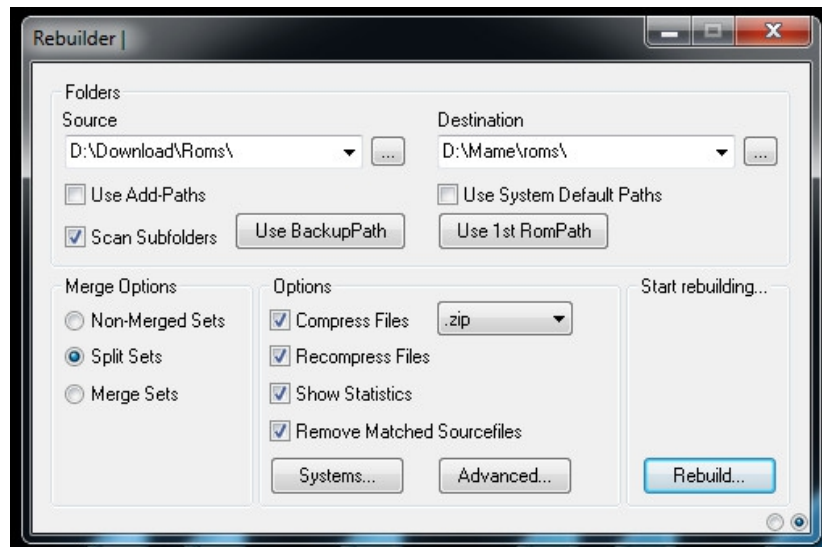

And we want to have the rebuilt sets in a zip-format.

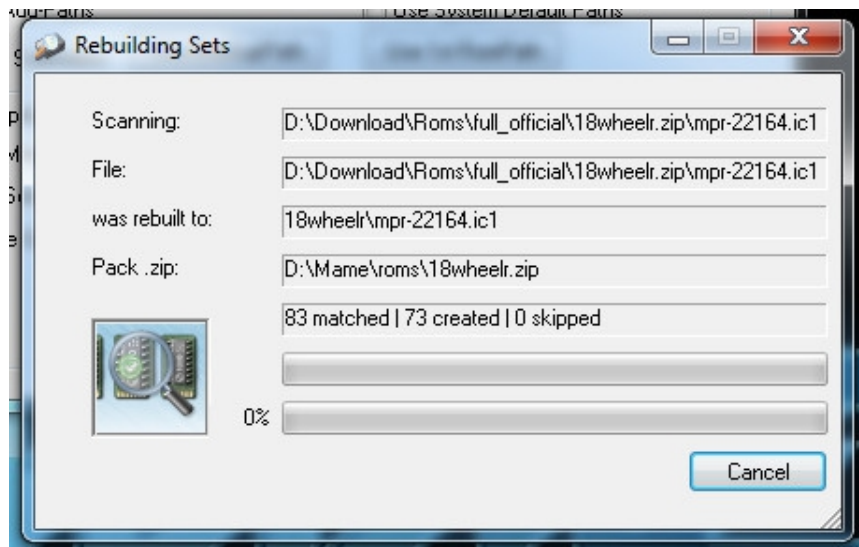

Ready for take off? Yeah click “Rebuild”

Rebuilding has started

We see that it has already found 83 matched and has created 73.

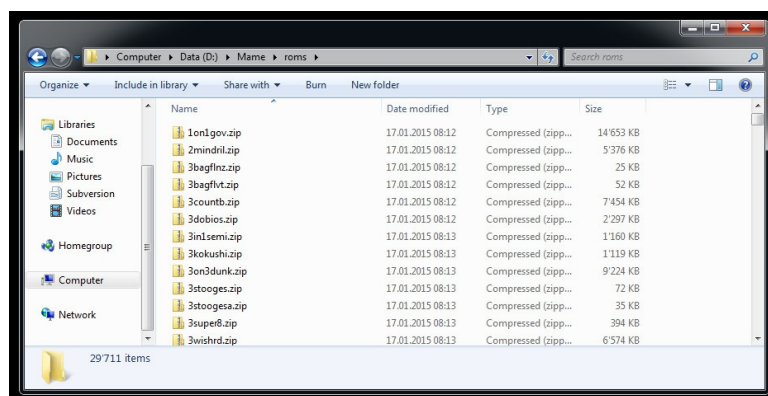

When it has finished again a statistics window appears.

Lets look at our download folderits empty → remember we have enabled “Remove matched....”

And in our MAME\Roms folder are now a lot of files :-)

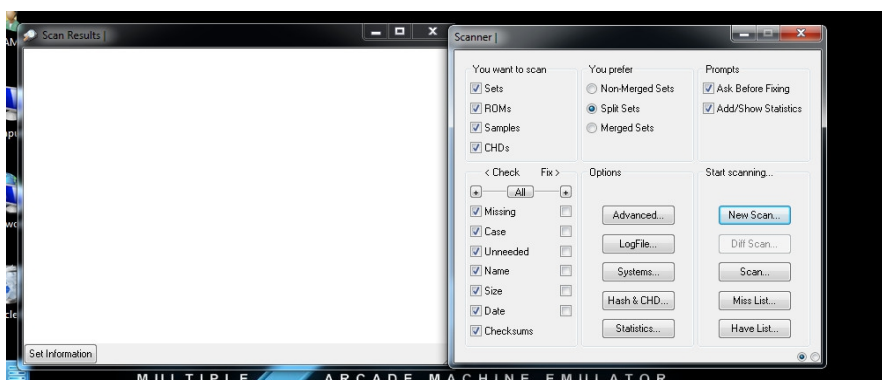

Yeah we have now rebuild 50 GB of files, but are they perfect now?

Is everything okay, do we have now a complete set? Let's use again the scanner option... and click “New scan”

! You can also choose now “Scan” because we have done already a first scan. Keep in mind when you choose “Scan” only reported bad/wrong/missing ROMs are scanned again.

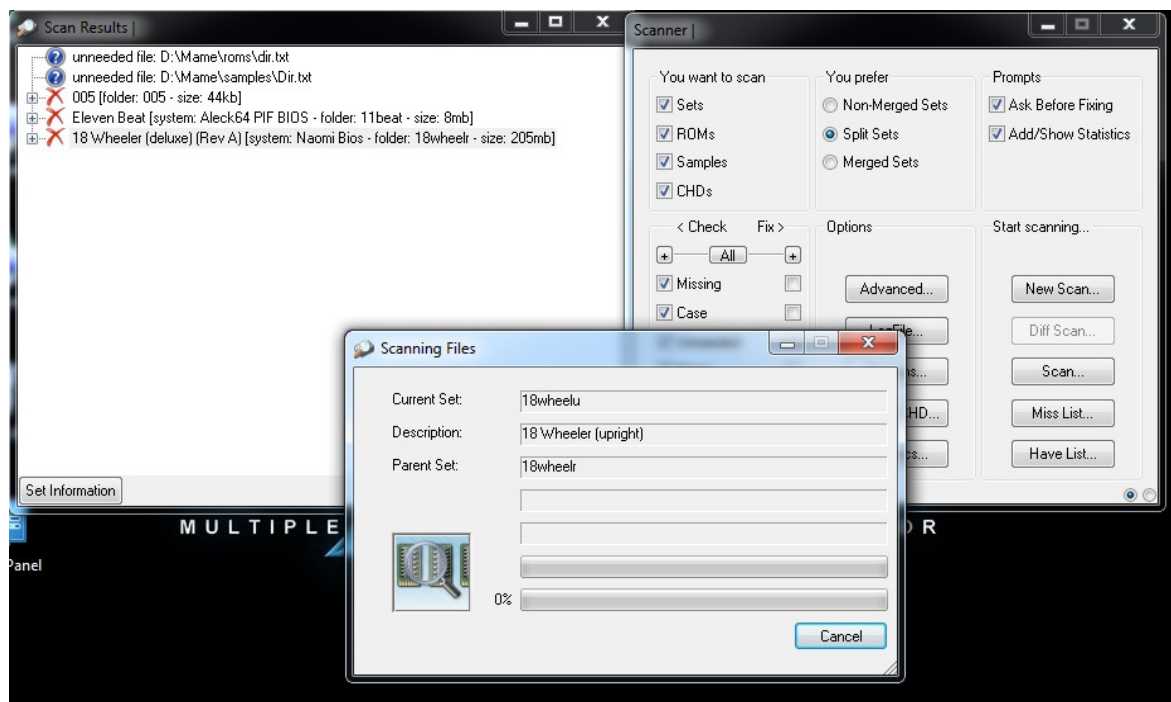

Again we received this message, yeah we have only rebuild ROMs.

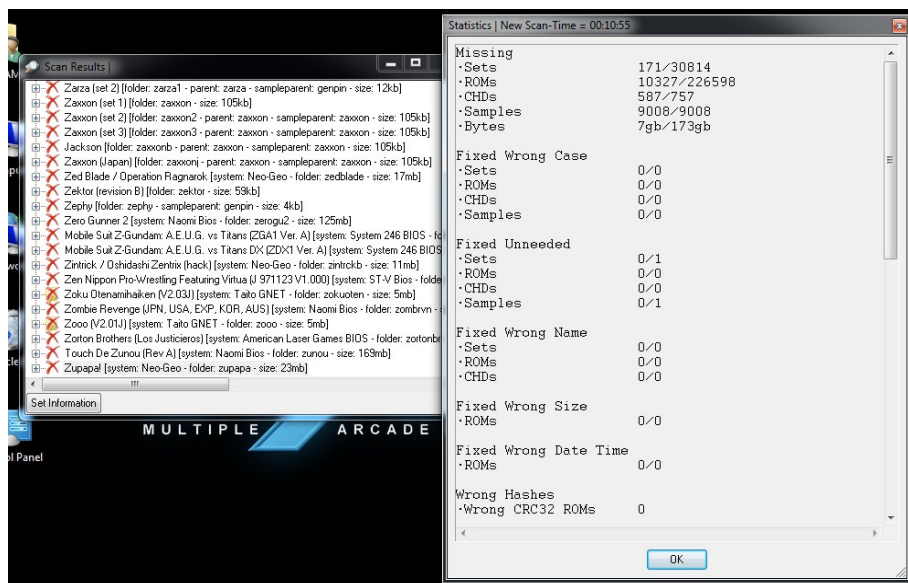

! Samples are stored in MAME only with their names and without a checksum. That's the reason why you can not rebuild the samples from a folder. You have to add them manually to the sample folder and verify if nothing is missing with the scanner.

The scan has started. Still reporting some missing

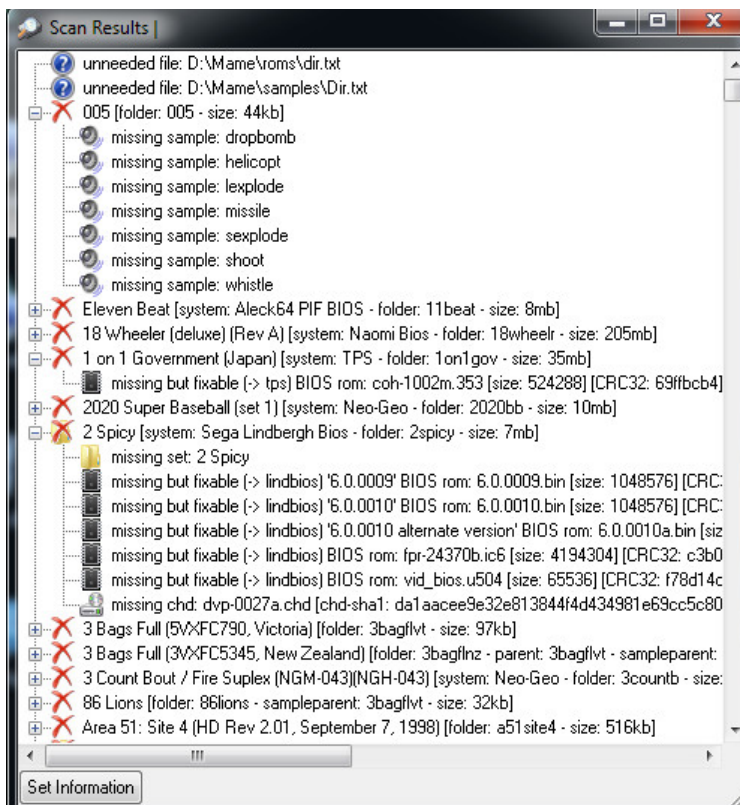

It has finished but why we have not a complete set?

Let's check the details in the Scan Result window.

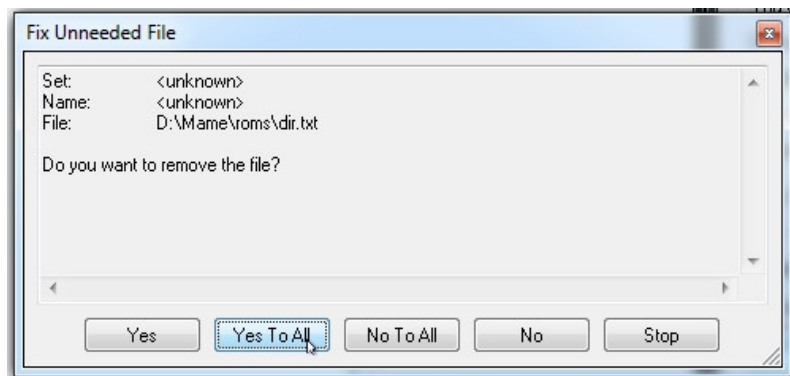

It lists the missing samples and CHD-files, some unneeded txt-files and some “missing but fixable”.

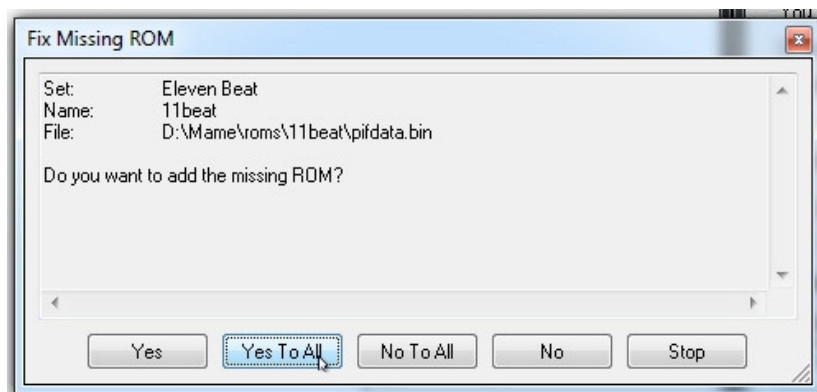

Now lets scan again and enable this fix options.

We have enabled “Ask before fixing” and now we received this question

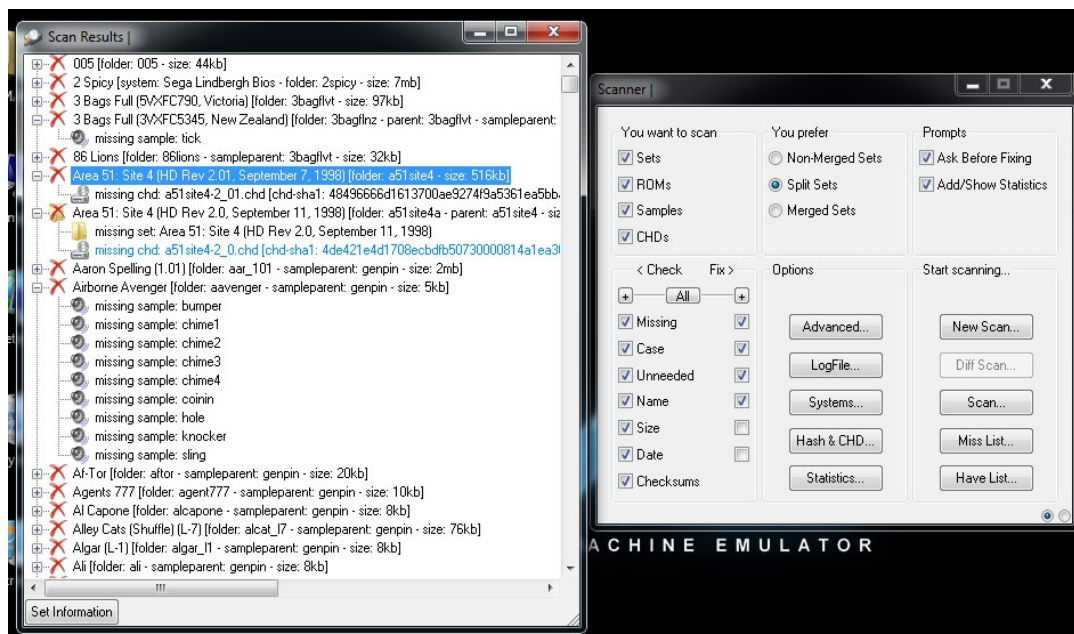

Say “Yes to all”. Next question “add missing” for sure → “Yes to all”

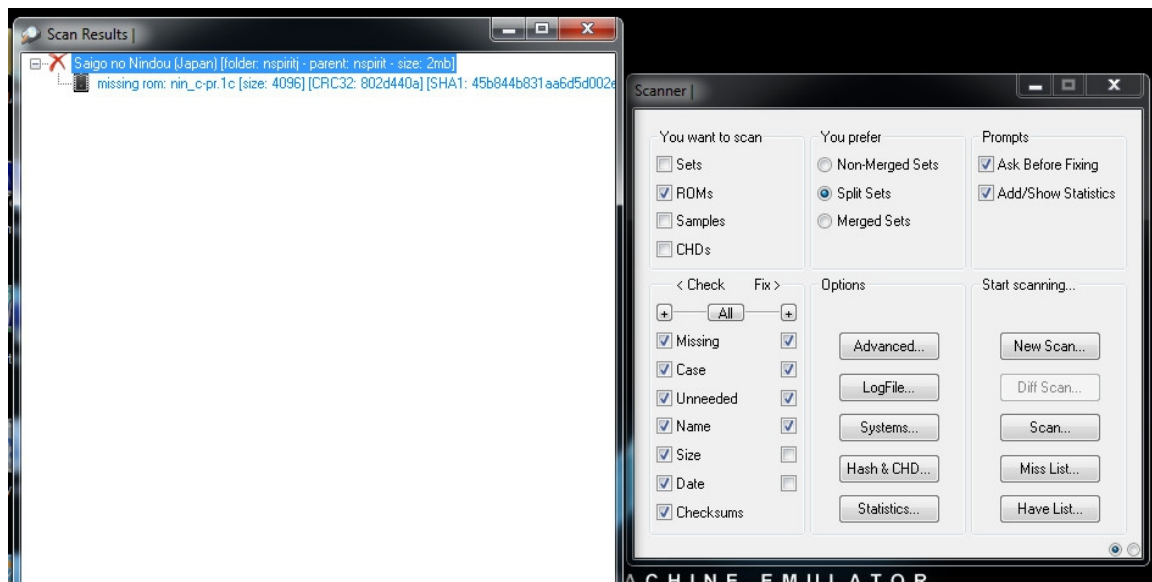

After the scan complete it shows us a better stats.

Missing Samples and CHD-files. Am I sure that nothing else is missing?

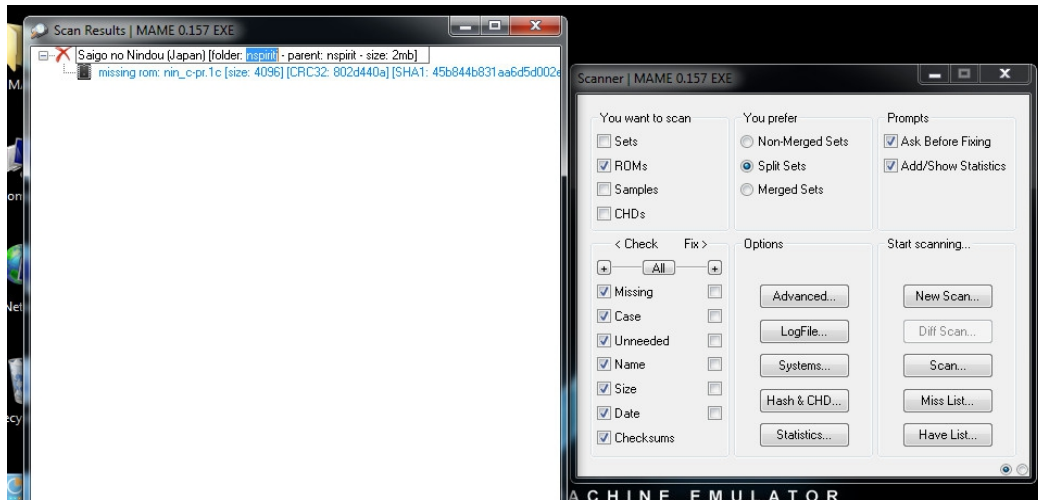

Untick “Sets”, “Samples” and “CHDs”. And there is still a ROM missing.

Strange seems that I have missed it to download :-)

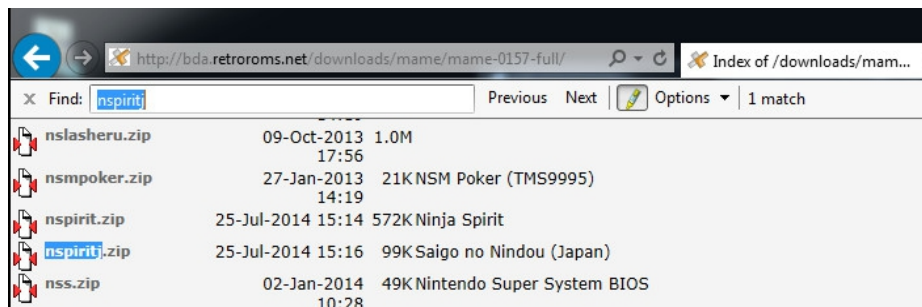

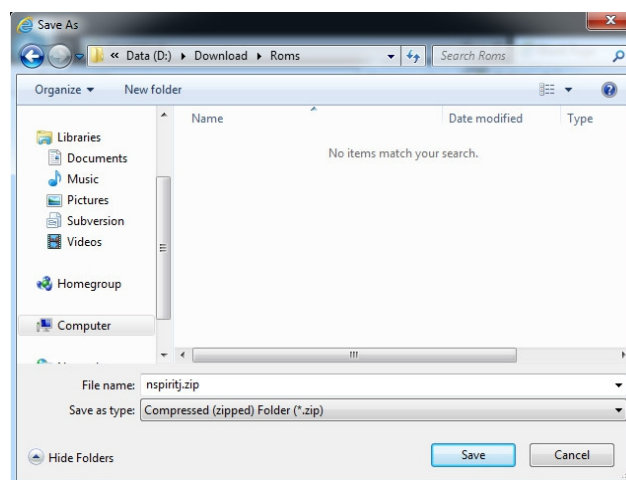

What is missing? A ROM inside a set called “nspiritj”.

Download this “nspiritj.zip” from Retroroms.net.....

.. to the download folder into “roms”

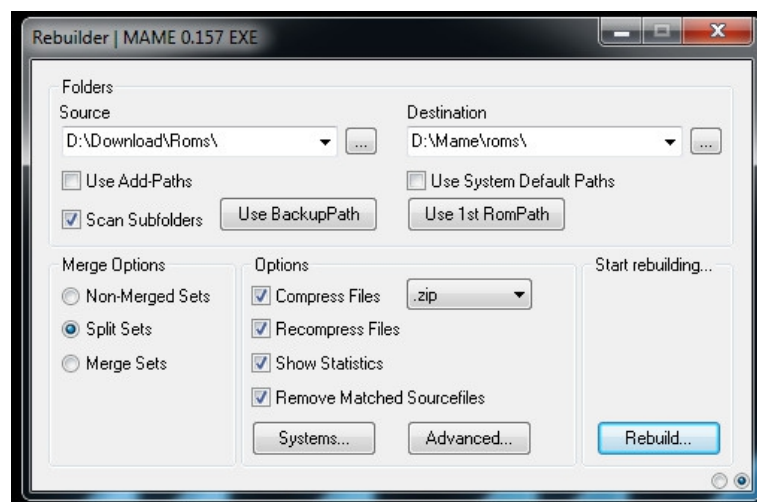

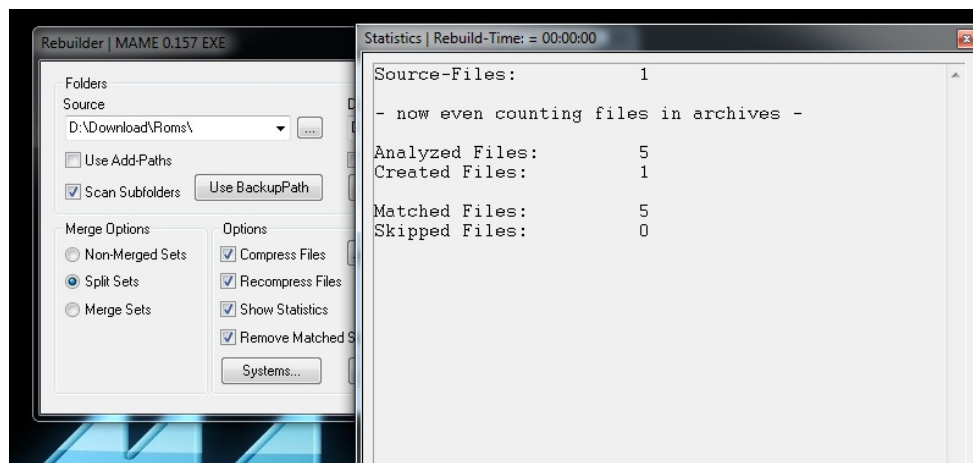

We must use the rebuilder again → choose rebuilder

The settings are still the same, let's “rebuild”

finished → it has created 1 file, looks good.

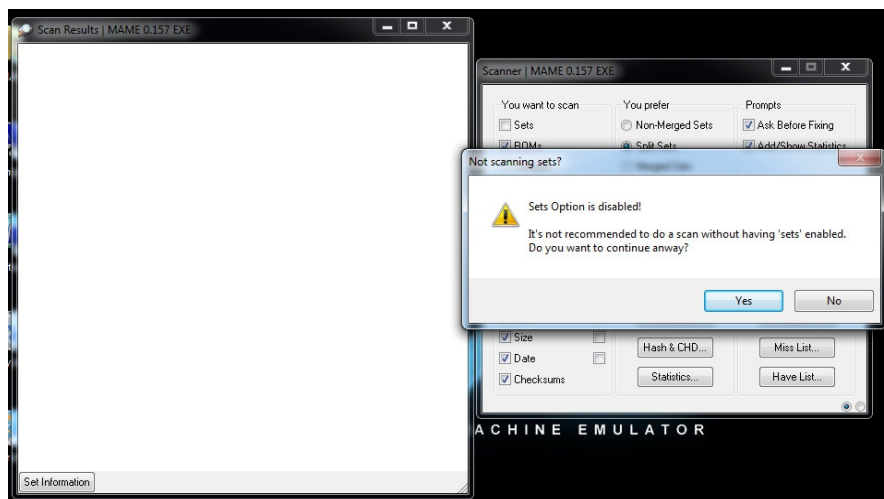

Now it is time for the scanner

Let's start the scan and now it complains about the disabled "Sets". Let's ignore that for now and click "Yes"

Yeah 0 ROMs missing

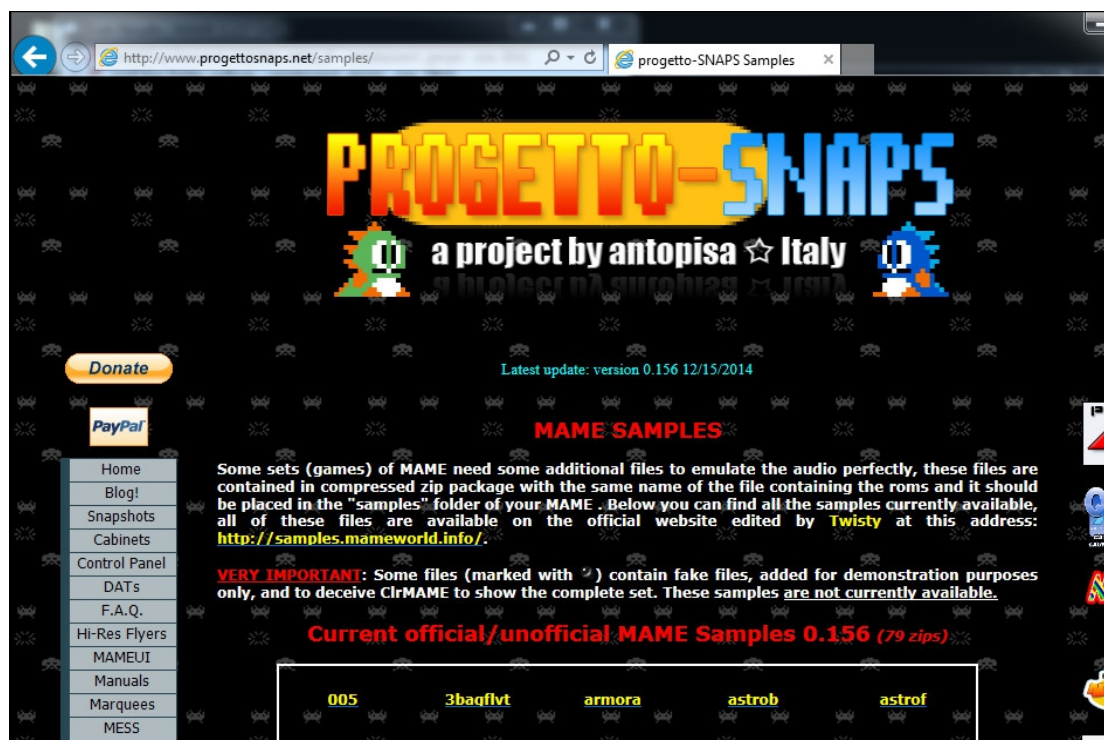

If you enables only “Samples” you see this stats

Lets fix that. Open a web-browser and navigate to the “Progetto-Snaps” site.

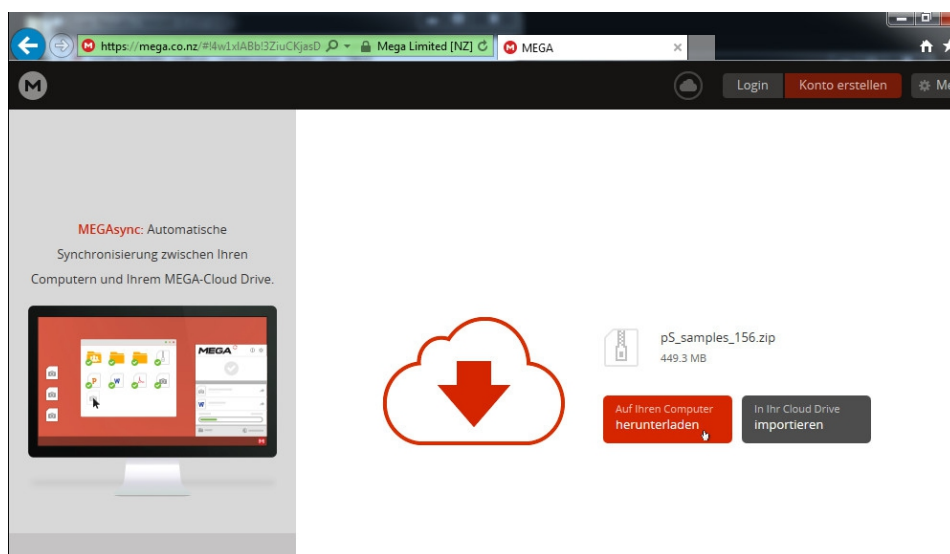

Under “samples” is at the bottom a link “Download Samples FullSet”.

Download it to your download-folder

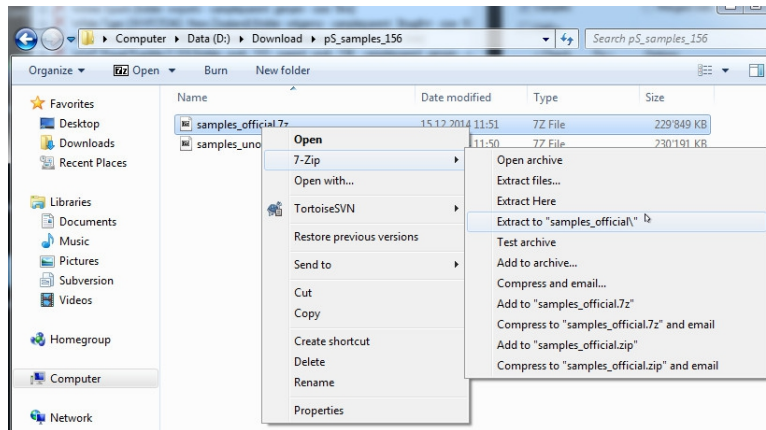

Extract the download file to a folder

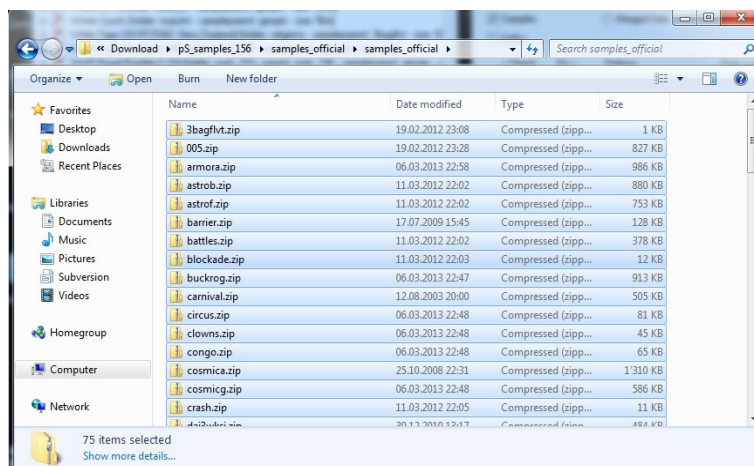

In this folder are now again two 7-zip files. Extract “samples_official.7z” to a folder

...and move the files from this folder “samples_official” to ...

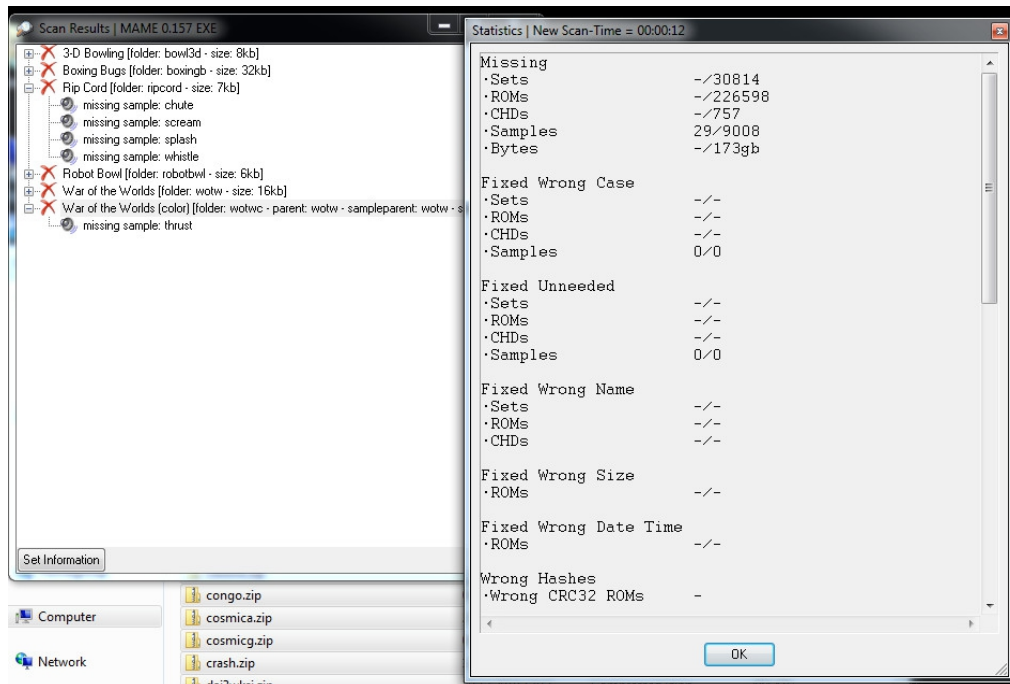

....the D:\Mame\Samples folder

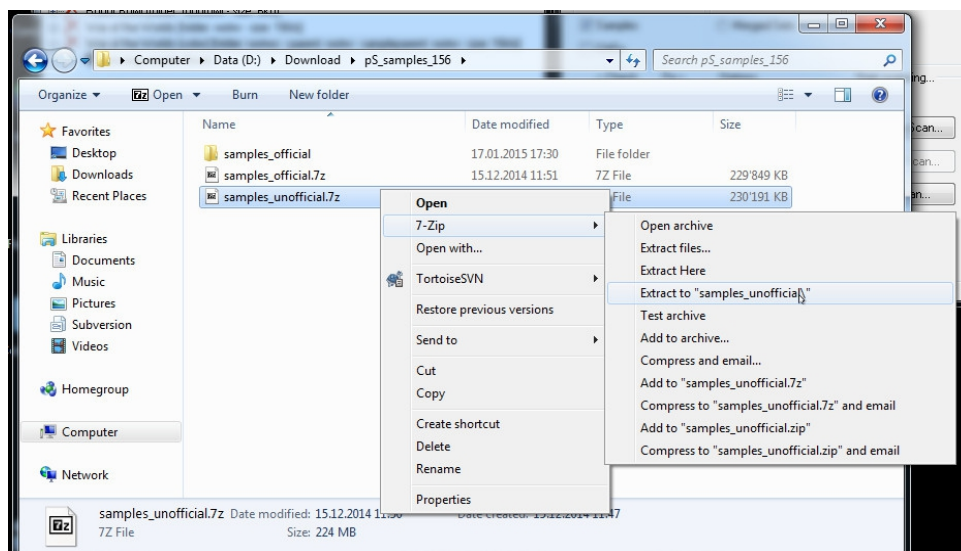

Scan again and wait we are still missing some samples :-)

Extract the other downloaded sample-file in the download folder.

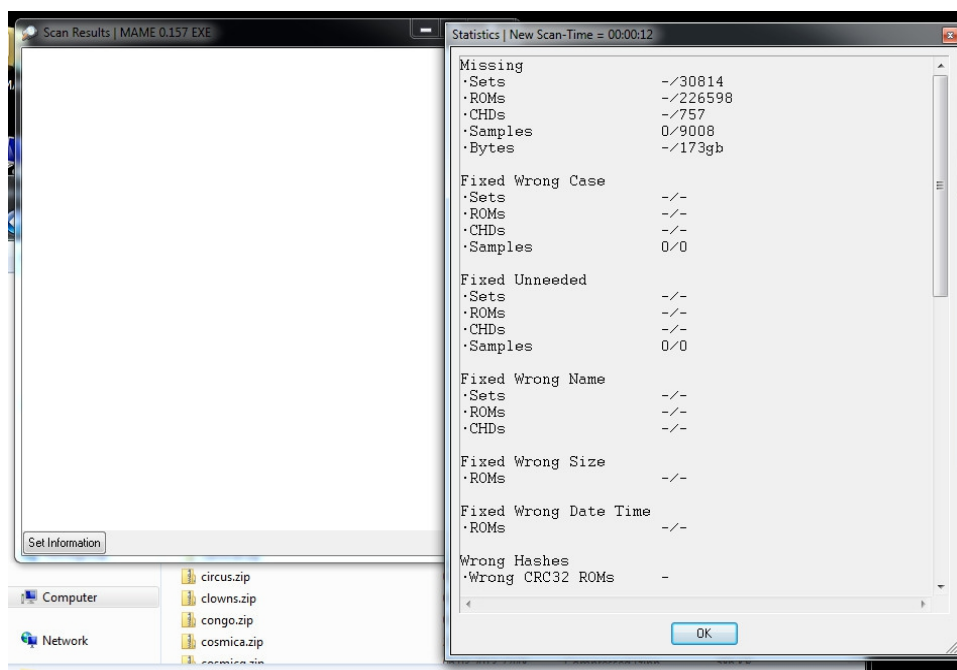

Search for the missing files in the extracted folder and move them to the d:\Mame\samples folder.

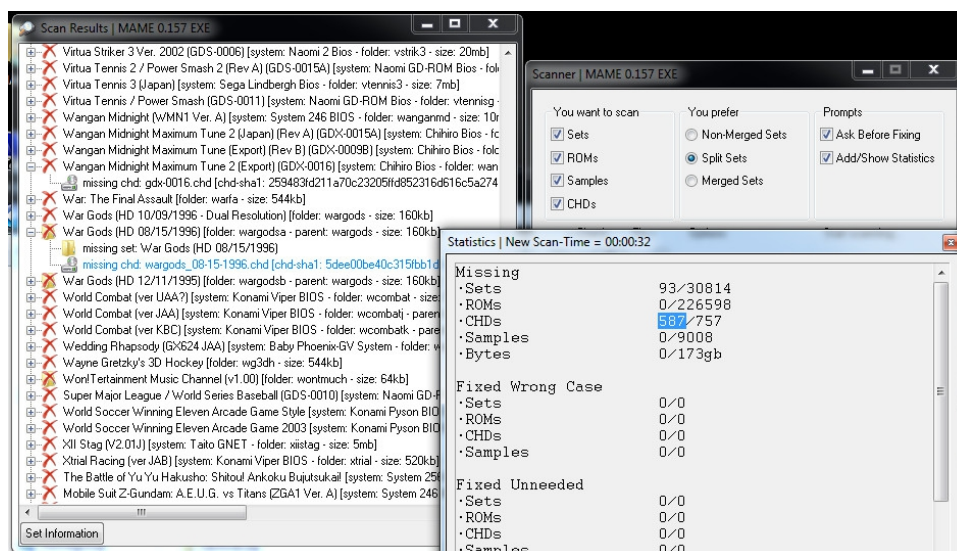

Say yes to “Replace”

Scan again and now you should have 0 missing samples.

When you enable now again all 4 options in “You want to scan” you will see that only CHDs are missing.

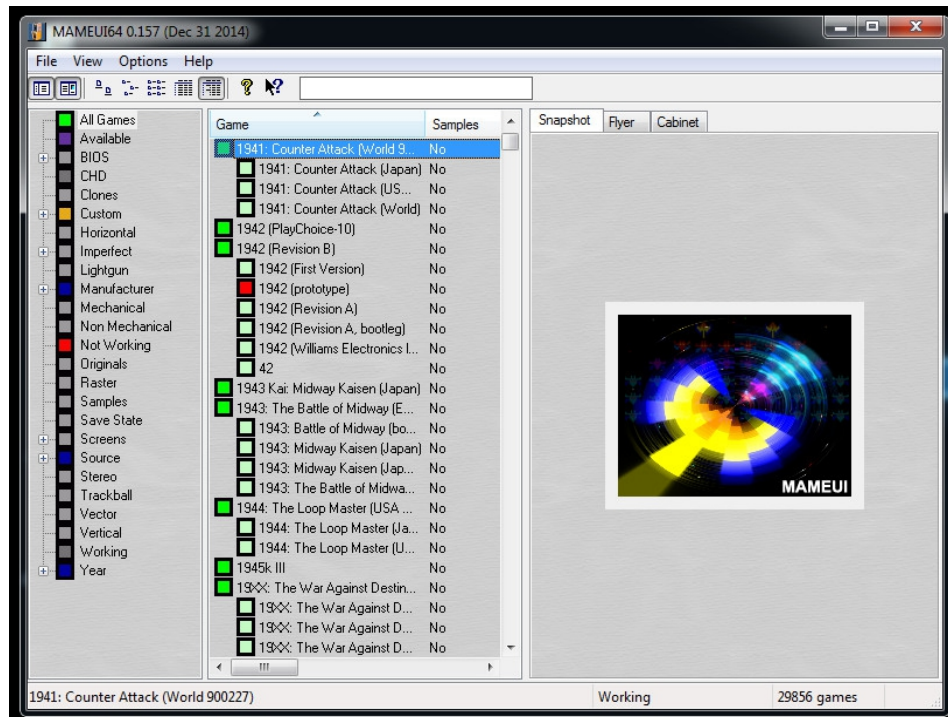

That's okay we can now use MAMEui and verify if we can start each game. Only those games should not work that requires one of the missing CHD-Files.

Let's start MAMEui

..and choose a game you like

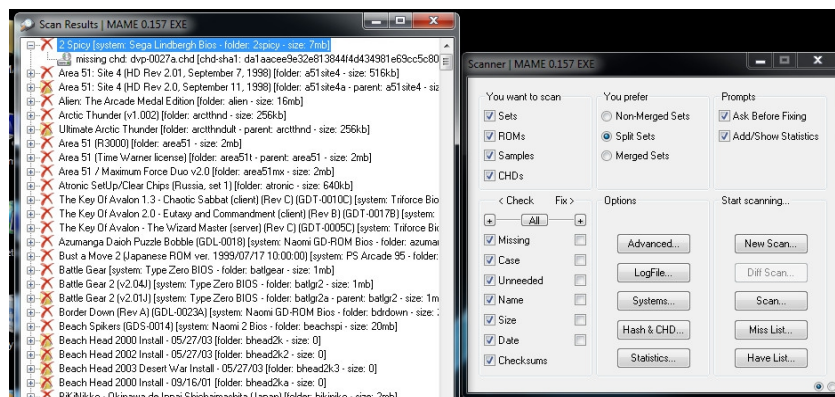

Yeah the game starts without complaining ...

Great great now let's have a quick look at those CHD-files.

When we scan with everything enabled we see all those missing CHD-files

We are now trying to fix one CHD-file as an example. Download the “2spicy” CHD-file from the internet (Using a torrent or Retroroms.net).

We have it now in our download folder.

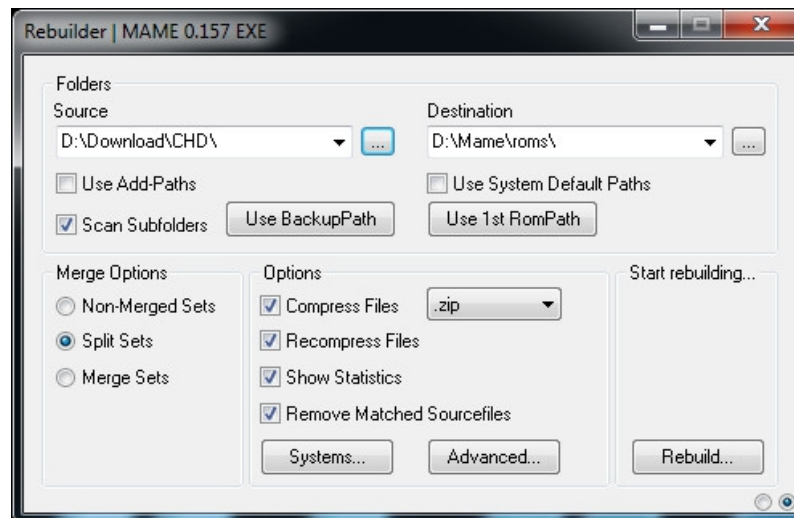

! Those CHD-files could be very big, the biggest are over 10 GB. A full CHD-set for 0.157 is around 380 GB.

We want to be sure that it is the correct version and we are using the rebuilder for that to prove.

And start the rebuilder

....What is that?

Nothing rebuild and it is still in the download folder

And not in the MAME folder ?

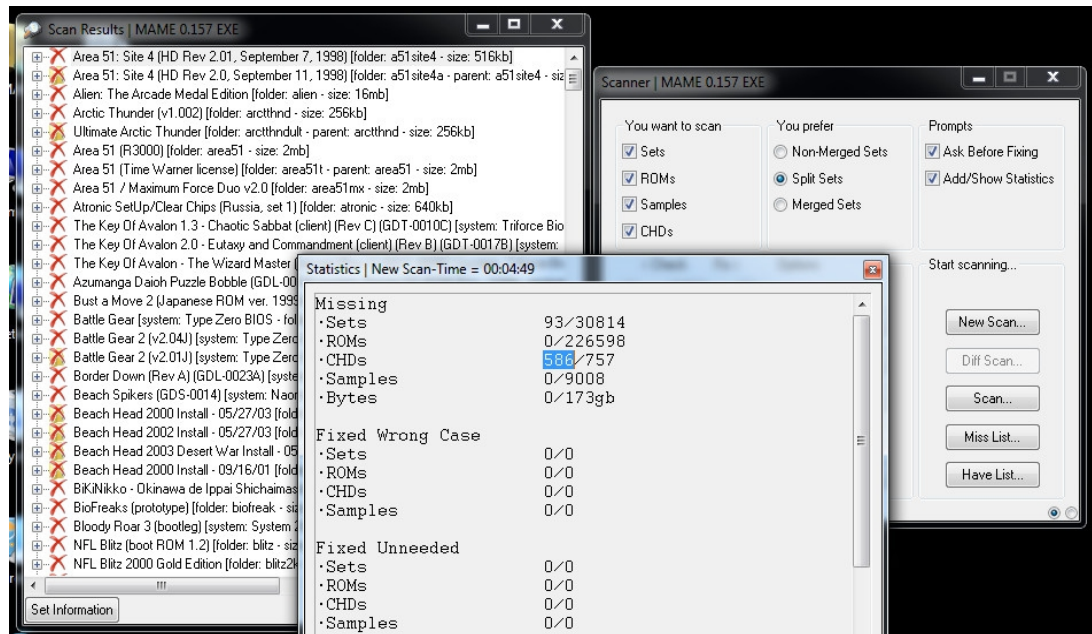

! Note from Roman (CLRMAMEPRO): Rebuilder is (currently) ROMs only. However the scanner can not only warn you about all kind of CHD issues, it can also move wrong placed and wrong named CHDs to their correct place. So you can simply move a CHD with any name to a rompath root (assuming you don't use that weird storing mode) and CHD + name + unneeded check/fix will tell you they are wrong placed and moves them to their correct setsubfolder.

Okay in that case we have to move the downloaded CHD manually. Move the folder “2spicy” to the d:\mame\roms folder.

We have now added 1 CHD and after a scan it shows us that we have 1 good CHD.

If you want to have a complete set (including all CHD) you must download and add them to the ROM-folder. After a scan you will see if you have a complete set.

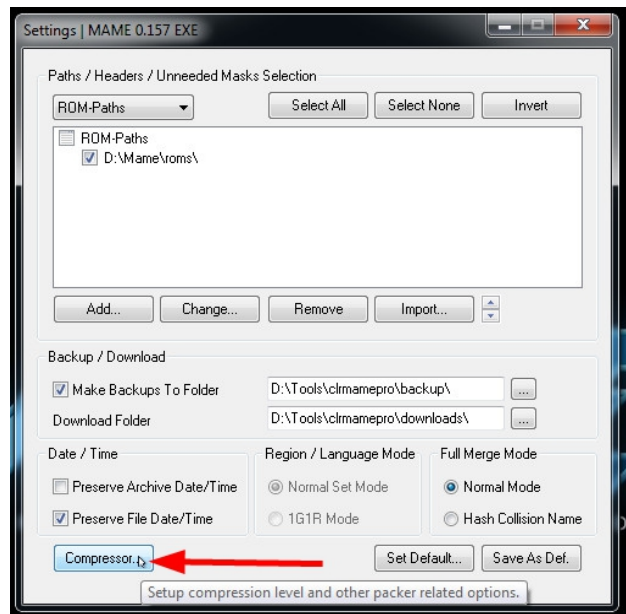

I have mentioned earlier that we can set some additional checksum verifying for the scanner. MAME has an own executable that can handle CHD-files (verify, upgrade, ..). I will show you now how we can enable that executable within CLRMAMEPRO and how does it work.

Go to the “settings”

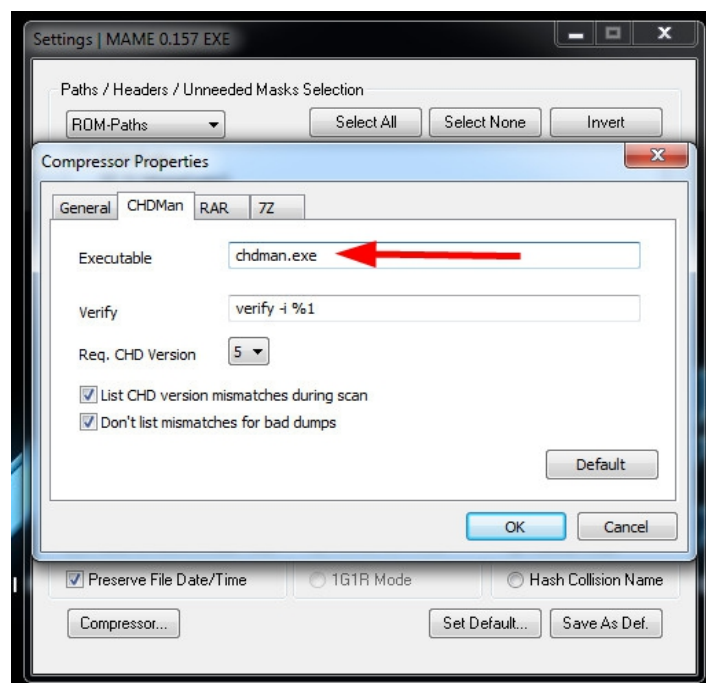

Under “Compressor”

There is mentioned an executable “chdman.exe”. Yeah exactly this one is from MAME.

Before we can use it we have to copy it from MAME.

Copy the “chdman.exe” from the MAME folder to

.. the CLRNAMEPRO folder.

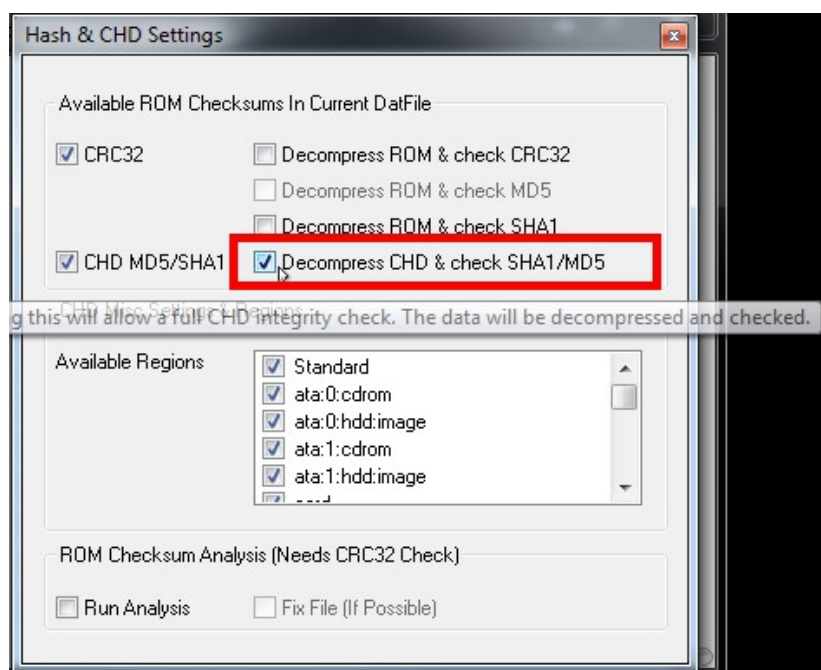

! Keep in mind to update this executable too when you have a new MAME build installed (if there are changes to the CHD handling!).

We have now this executable and we are enable it now in CLRMAMEPRO in the settings under “Hash & CHD”

enable “Decompress CHD & check SHA1/MD5”

When we do now again a scan it will check each block of the CHD for integrity with this external executable from MAME.

**! Please note that scan takes much longer but you are at the end
• 100% sure that everything is fine.**

Scanning with DAT-files

Next topic is when we have a DAT-file (downloaded from the Internet) for using in CLRMAMEPRO instead using the build-in “create DAT” function. We start CLRMAMEPRO

Choose “Add DatFile”

With DFC we have created a DAT-file, we want use that as our example.

Load that DAT-File

Stores it to the MAME profile path

And load this added DAT-file

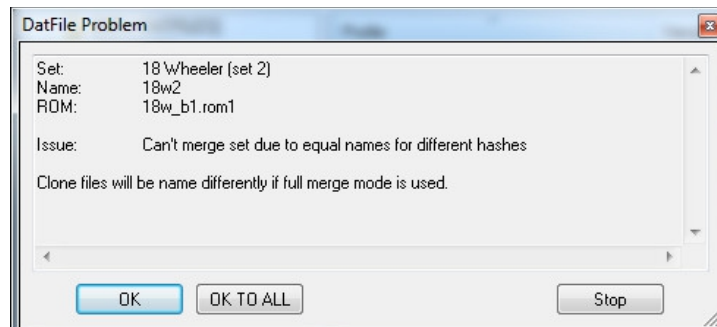

with “default” settings

Click “OK to ALL”

Go to the Settings

Set the source to our mame\roms folder

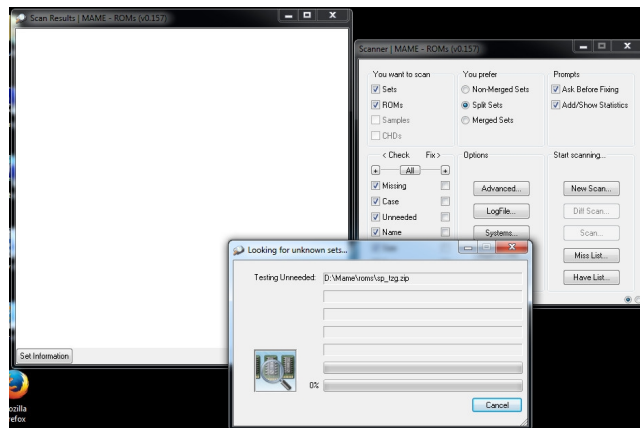

time for our scanner

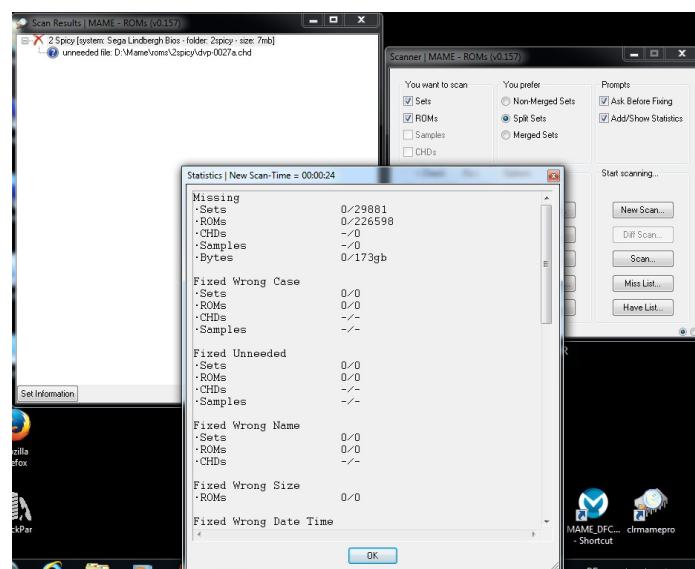

scanning scanning scanning ...

Yep nothing missing but why is our CHD listed as “unneeded”?

! Please note that we can scan only “Sets” and “ROMs” because in this DAT-file is nothing else available. We have used “Split Sets” in our mame\roms folder while we have created it. Be sure that you use the same in future scans, otherwise it will try to rebuild it

Going back to the question “Why is our CHD listed as unneeded”. We have scanned this ROM-folder with a DAT-file that has only ROM-information available. Be really sure that when you have enabled the fix-option for unneeded files that you are sure to remove only wanted files.

In that case I would have separate folder for ROMS and CHDs. You can set in MAME more than one folder for the ROMs it should looks for.

With available DATs it is easy to scan sets. Be aware where you download DATs and what they are for. Using a unknown DAT on your ROM-folder with fix-options enabled can damage your collection → be always sure that you have enabled “Backup” in the scanner settings.

Rebuilding with DAT-files – doing a full update

We have all our MAME-ROMs for V0.157 in our ROM-folder

Name	Date modified	Type	Size

In the meantime a new MAME version is available. I will show you how we can update our set to match the new V0.158.

Download the new version from MAMEdev.com to our download-folder

Double-click it for extracting and point it to our MAME-folder

There are several files that needs to be overwritten (Included in the 0.157 release).

Normally you can overwrite them all. But when you have customize a file for example this X-Arcade cfg-file for a special reason then you should not overwrite it ;-)

Change to the MAME-folder and check that the executable is for 0.158.

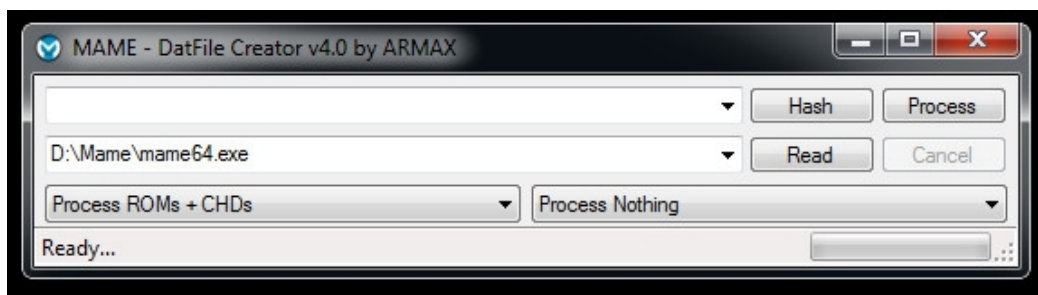

We have now updated our command-line version of MAME. We want now to update our ROM-folder to match this new version. Start DFC as we want to use that created DAT-file later.

Point it to our MAME 0.158 executable in the read-field and select “Process ROMs + CHDs” in the left panel. Start “process” ...

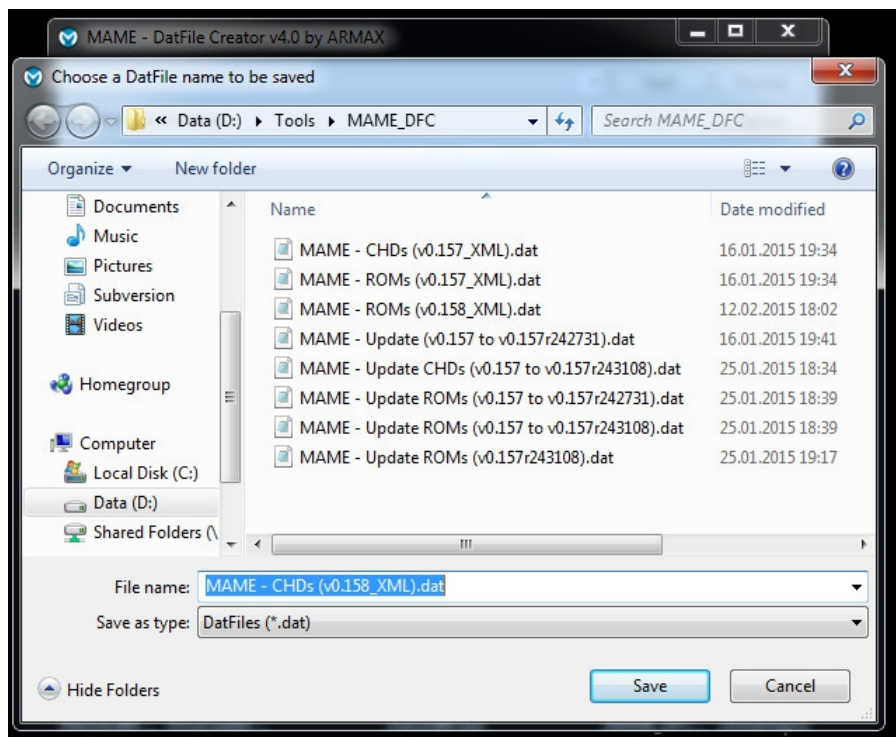

.. and save the “ROM-Dat”

Do the same for the CHD-DAT-file

Now we have the DAT-File close DFC and start CLRMAMEPRO

Add now the DAT-File in the profiler

Choose the DAT-File “MAME - ROMs (v0158_XML).dat” from the DFC program folder.

Store the DAT into the “MAME” folder

And load it into the profiler

for CLRMAMEPRO it seems that this DAT is an update to an existing one.
Yeah that's right, we can choose “Yes”

! Update means that it copy all the settings from the old DAT-File and deletes the old one afterwards. Normally you don't need an old DAT when you have updated a ROM-Folder (it is useless).

Those DAT-file-Problem questions are coming, say “OK to all”

Go into the “Settings”

Verify the ROM-Paths, as it is an update it should be set correctly

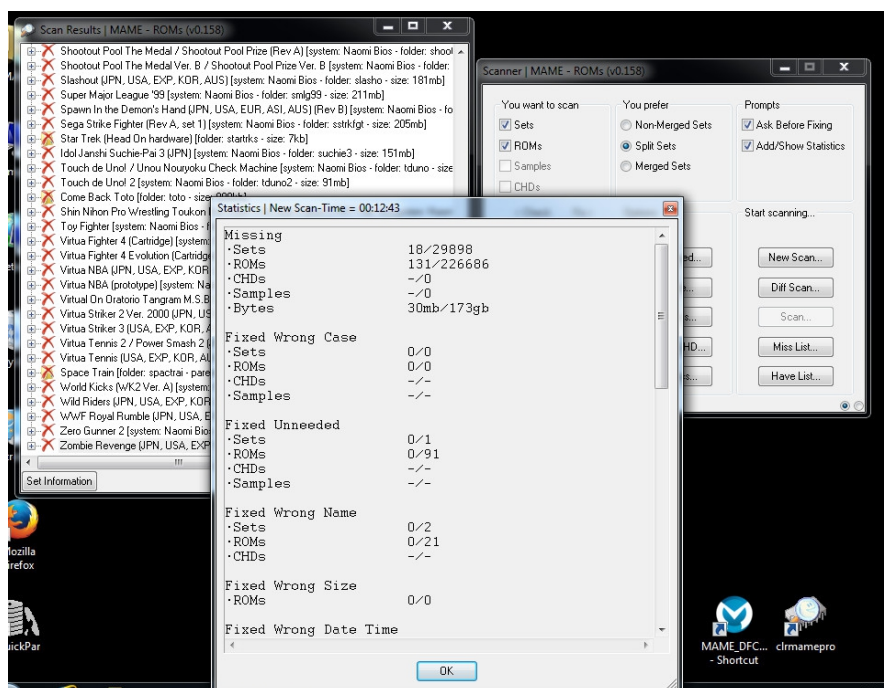

We use now the “New Scan” ..(and nothing is enabled under “Fix”)

We have now the result, a scan with a DAT-file for 0.158 for our 0.157 ROM-folder.

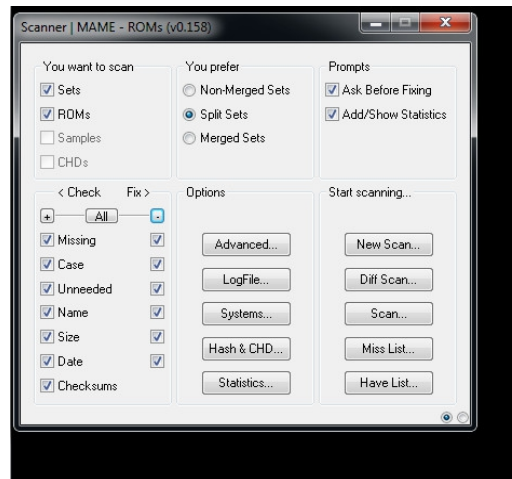

When we look at the result windows we can see which files are unneeded, missing or have a new name.

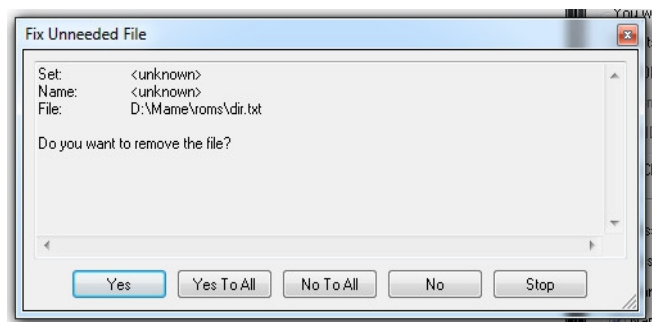

We do now a new scan with all the available “fix” option enabled! Yes we are doing now changes in our ROM-folder! Files are being renamed, repacked or deleted (if you have enabled “backup” → moved to the backup folder).

The following questions → say “yes to all” → we want to clean up and update our ROM-folder.

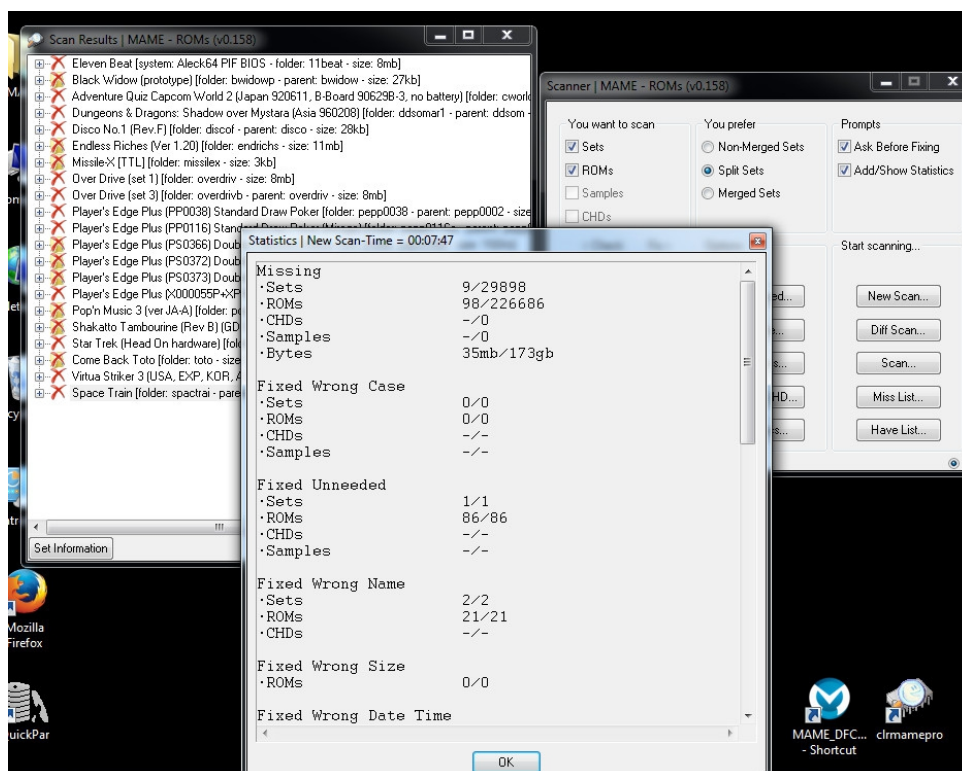

MAME/MESS The Guide

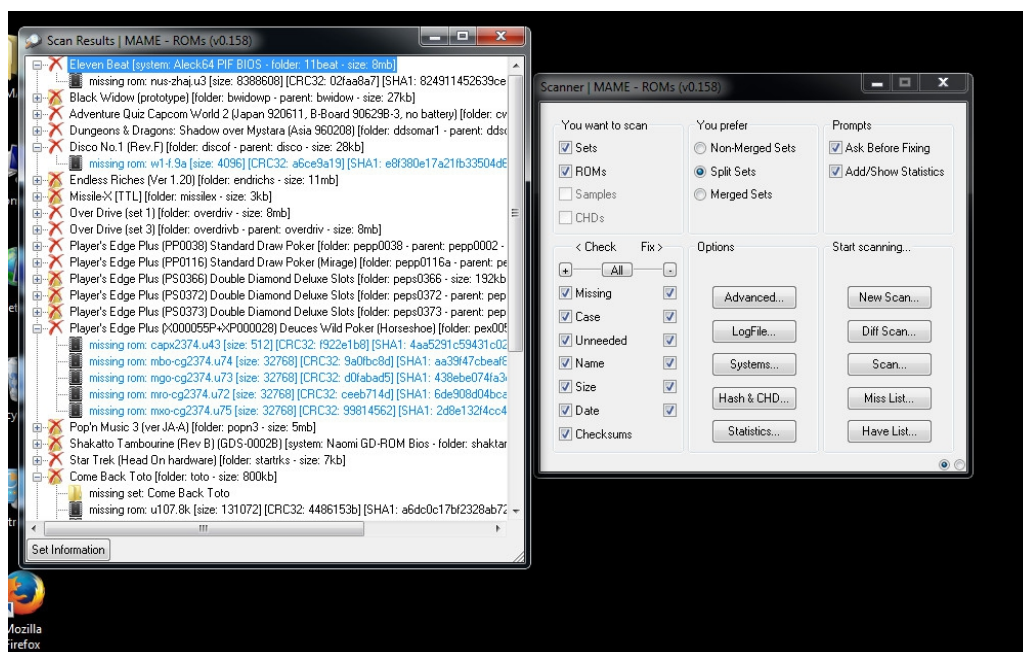

After the scan has finished our ROM-folder looks better ;-)

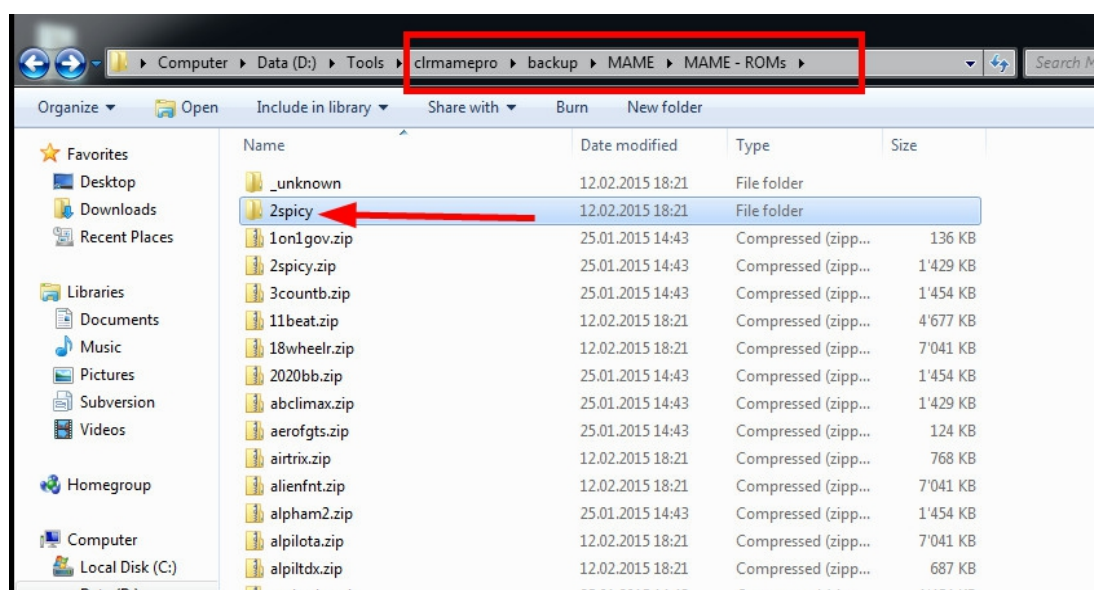

Now when you are looking into the result windows you should only find “missing” entries...

When we are looking into our ROM-folder it looks good. Wait wait wait a moment where is our CHD-file? Ahh yes we have a ROM-Dat file and scanned the folder with the fix-option “unneeded” enabled. CLRMAMEPRO has moved all unneeded files into his backup folder.

We leave this CHD-file there and want to correct that later that those CHD files are stored in another location.

For the updating we need the new/added ROMs. Download them from the Internet and we store it into this folder.

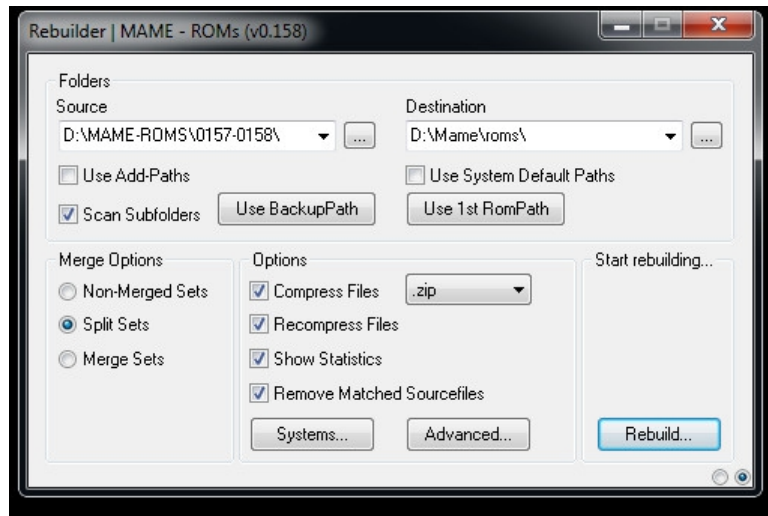

So we have everything, a cleaned up ROM-folder and the new ROMs in a separate folder. We need now the rebuilding function from CLRNAMEPRO again. Choose “Rebuilder” (still our “Mame - ROMs (v.0158_XML).dat” loaded)

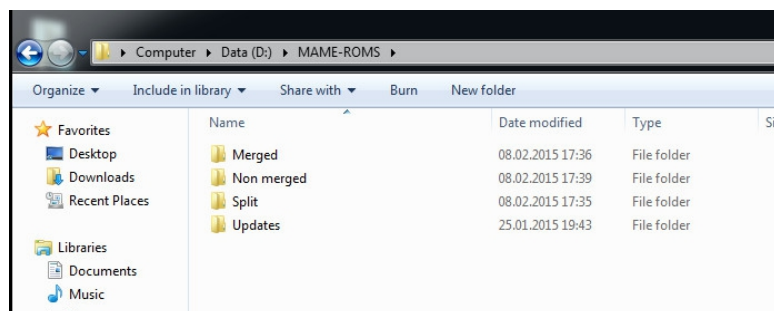

Point our source folder to the update ROMs and do a rebuild.

Scan result says 93 created, sound good.

The rebuild process has used all ROMs that we have downloaded. The download folder with the update ROMs is gone ...(remember “Remove...”)

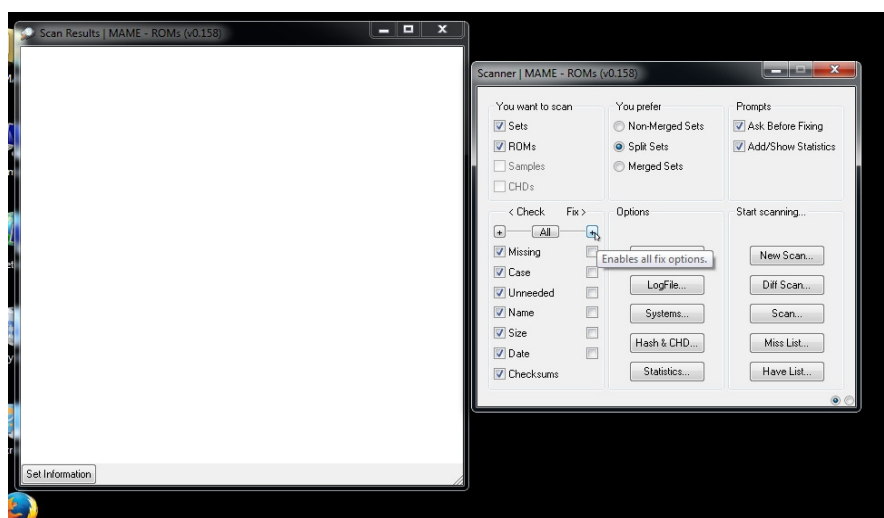

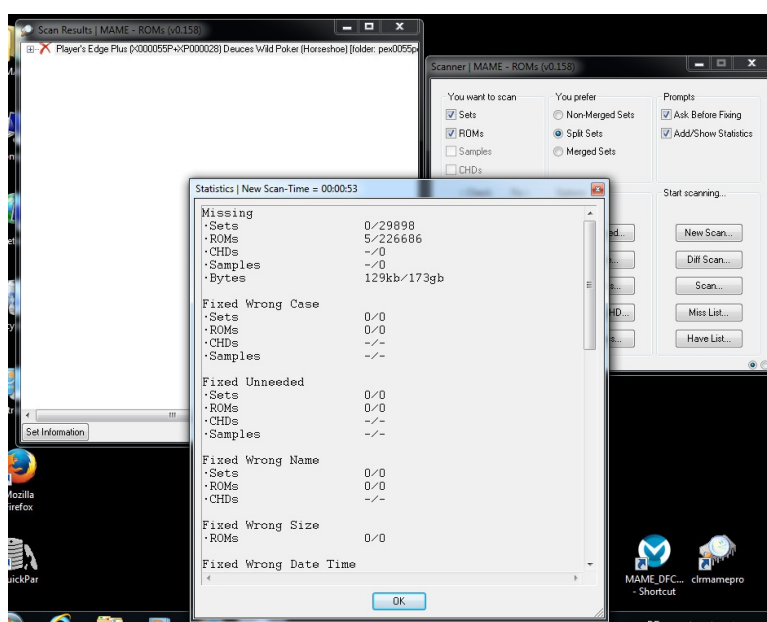

We scan our freshly rebuilt ROM-folder again ...

We disable all “fix”-options. And do a new scan.

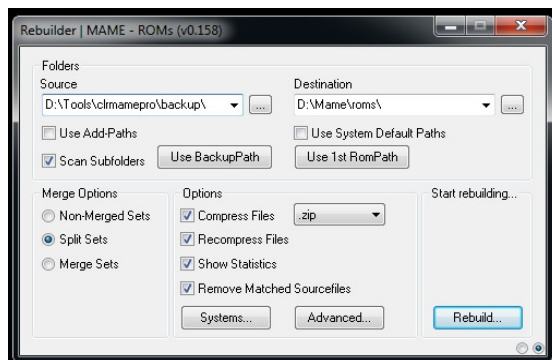

The result is not bad, but also not perfect. It seems that 5 ROMs are still missing.

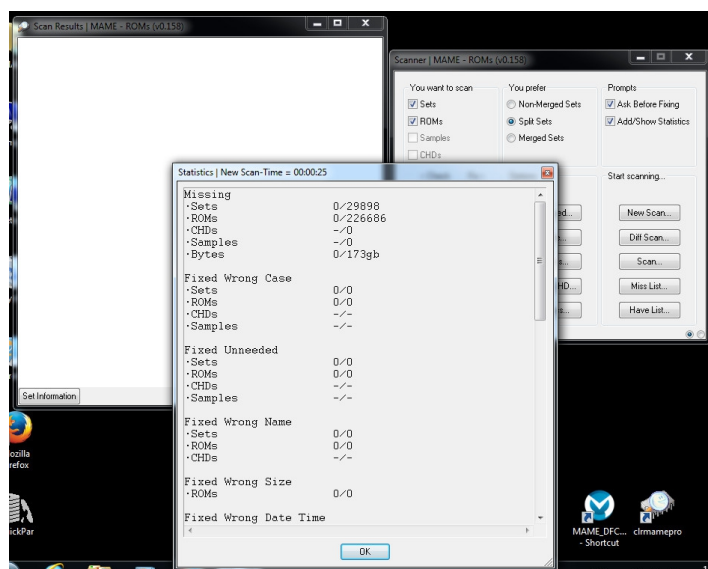

Hmmm strange strange. Let's search for the missing file in the “backup” folder of CLRMAMEPRO.

After the scan the result windows tells us that it has created 5 files :-)

Scan again and wow we have now a complete 0.158 ROM Set.

The ROMs are now perfect and we have our CHD-folder removed in the backup folder of CLRMAMEPRO. Let's change that for the future that It will never happen again.

Create a folder “CHD” in our MAME-ROMS folder.

And move the CHD from the Backup folder in CLRMAMEPRO to this folder.

Good :-)

We move now also all MAME-ROMs away from the MAME-Program folder into an own ROM-folder. Sometimes it easier to have them stored outside the program folder ;-)

The screenshot shows a Windows XP desktop with a taskbar at the bottom. The 'Start' button is on the left, followed by icons for Internet Explorer, a folder named 'Data (D:)', and a folder named 'Mame'. The 'Data (D:)' folder is open, showing a list of files and folders. The 'Mame' folder is selected, and its contents are displayed in the right pane. The files listed are: DIRECTORIES.ini, e1_extras.ini, EmuLoader.exe, EmuLoader.ico, EmuLoader.ini, GAMEINFO.ini, history.dat, jedutil.exe, Idresample.exe, Idverify.exe, jedutil.exe, mame.ini, mame64.exe, mame64.sym, Mameui.chm, MAMEUI.ini, Mameui64.exe, nlttool.exe, romcmp.exe, SEGAModel2.xml, and SEGAModel2.v1.0. The 'mame.ini' file is selected, and its details are shown at the bottom: 'mame.ini', 'Date modified: 1/1/2008', 'Size: 7 KB'. The 'mame.ini' file is open in Notepad, showing the following configuration options:

```
#
# CORE CONFIGURATION OPTIONS
#
readconfig          1
writeconfig         0
#
# CORE SEARCH PATH OPTIONS
#

#
# CORE STATE/PLAYBACK OPTIONS
#
state               0
autosave            0
```

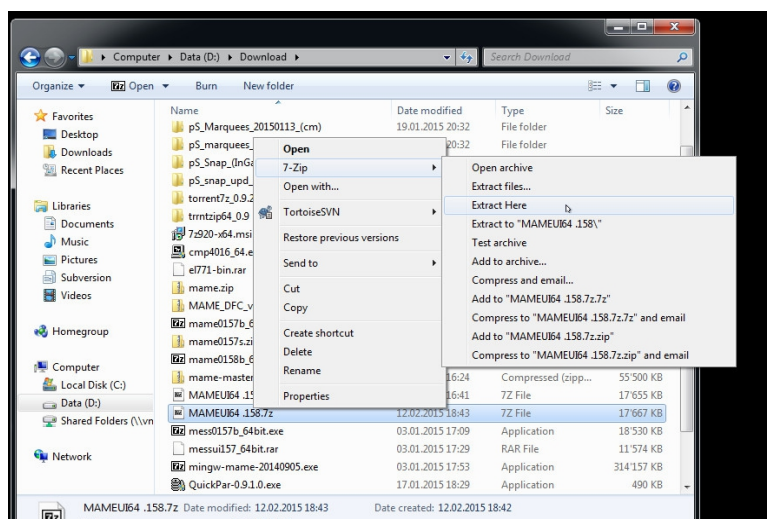

The screenshot displays a Windows XP desktop environment. In the foreground, a file explorer window is open, showing the contents of a folder named 'MAMEui'. The folder contains various files, including configuration files (.ini), executables (.exe), icons (.ico), a help file (.chm), and a model file (.xml). The file explorer's left pane shows the 'Computer' view, with 'Local Disk (C:)' selected. Below the file explorer, a Notepad window is open, displaying the contents of the 'MAMEUlini' file. The file is a configuration file for the MAME emulator, containing sections for 'APPLICATION OPTIONS', 'DISPLAY STATE OPTIONS', and a list of various settings like 'default_game', 'default_folder_id', 'show_image_section', 'full_screen', 'current_tab', 'show_tool_bar', 'show_status_bar', 'hide_folders', 'show_folder_section', 'show_tabs', 'hide_tabs', 'history_tab', 'sort_column', 'sort_reversed', 'window_x', 'window_y', 'window_width', 'window_height', 'window_state', 'text_color', 'clone_color', 'custom_color', 'list_mode', 'splitters', 'list_font', 'column_widths', and 'column_order'. The Notepad window's title bar indicates it is editing 'MAMEUlini - Notepad'.

We have updated the command-line version of MAME and the ROM-folder. Be aware that we have still “old” program that should use the new ROM-folder. MAMEui and Emuloader are still not for V0.158 updated!

! Don't mix up emulators with different versions to share a single ROM-folder.

Download MAMEui from the website and extract it into a folder.

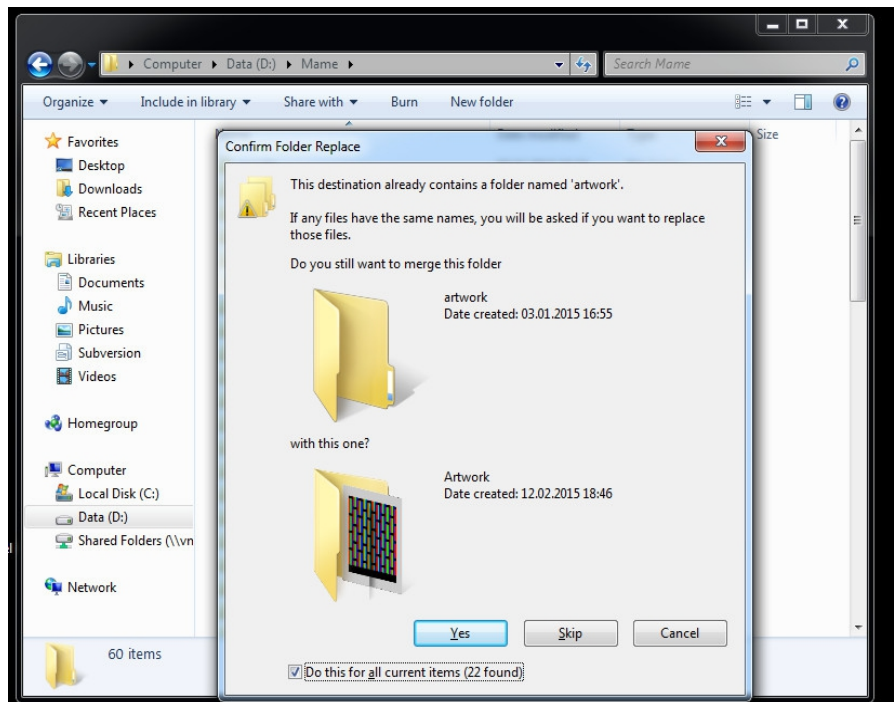

Move all the files from the extracted folder

..to the MAME folder and overwrite duplicate files.

Finished “updating” MAMEui → start the program.

MAMEui starts

And have we not something changed that MAMEui needs to know? Yes sure we have moved our ROMs to an own folder and store the CHD separate.

Change that under “Options - Directories” and add those two path.

Remember that you should hit “F5” (refresh) each time after an update that MAMEui could scan for changes within the ROM-folder.

MAMEui has btw stored that two path in the directories.ini.

Let's try to run a game....

..and it does work.

We have forgotten to test our command-line version of MAME if we can still start a game with the new path.

Yes and “Donkey Kong” is climbing again...

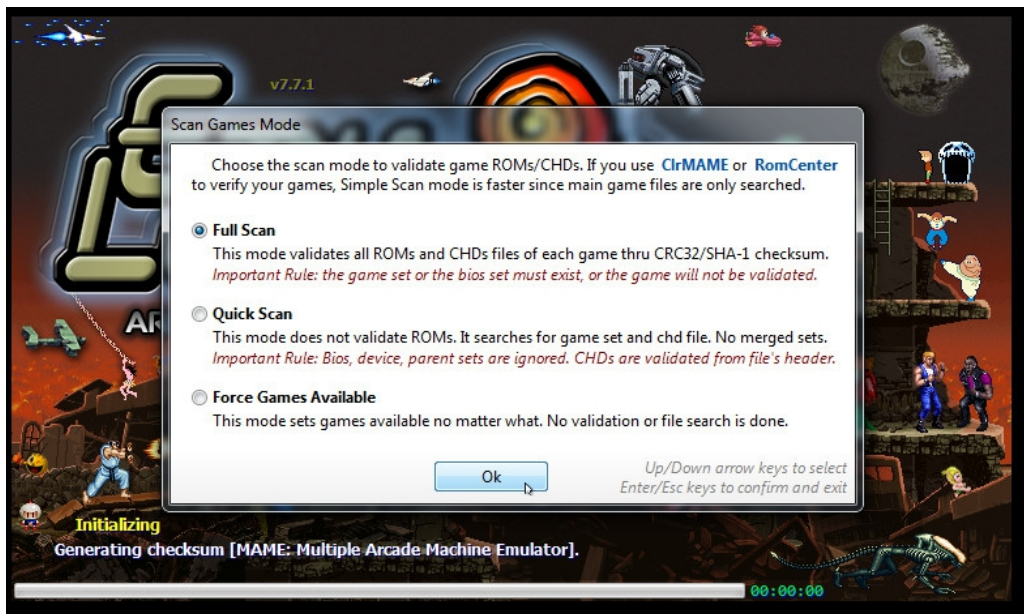

We have now MAME updated (command-line and MAMEui) and we need to “refresh” EmuLoader. When we start EmuLoader it has detected that the MAME.exe is a different one. Say “Yes” to this question.

To be sure that everything is detected right we choose a “Full scan”

After the scan EmuLoader is ready.

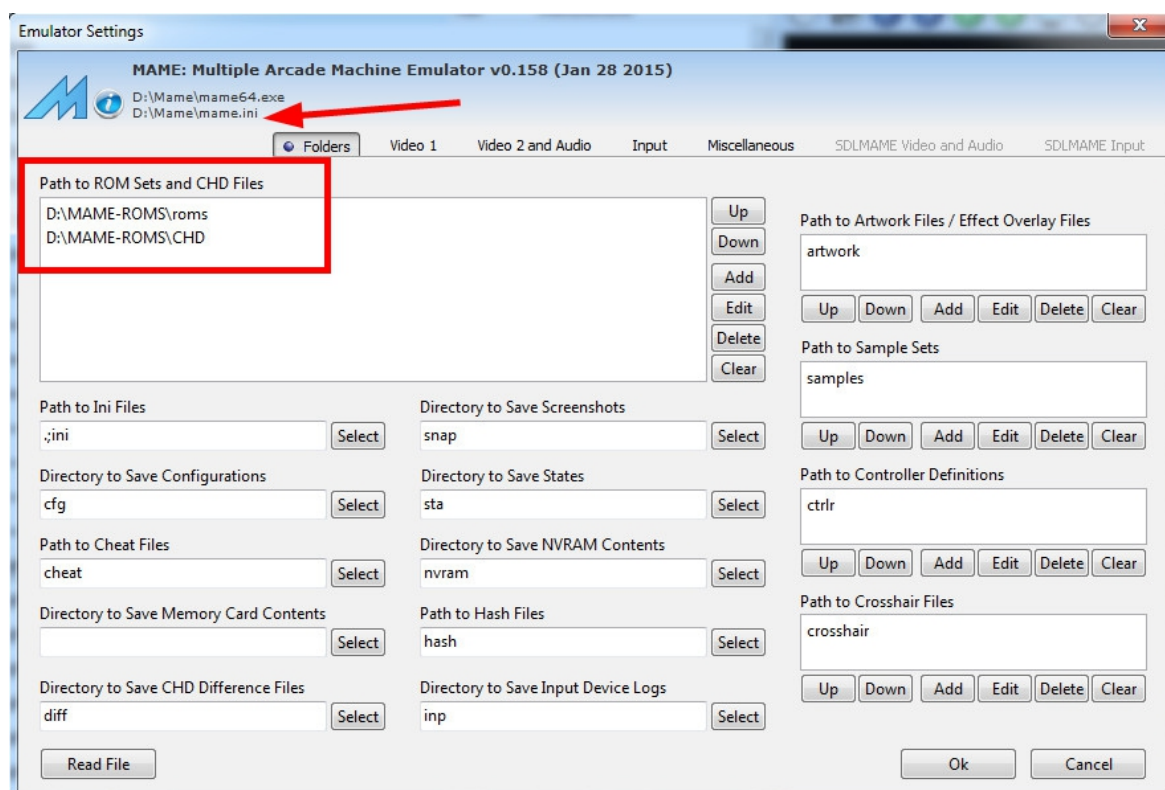

And yes we have changed our ROMs-folderopen “Main menu - Emulator setup”

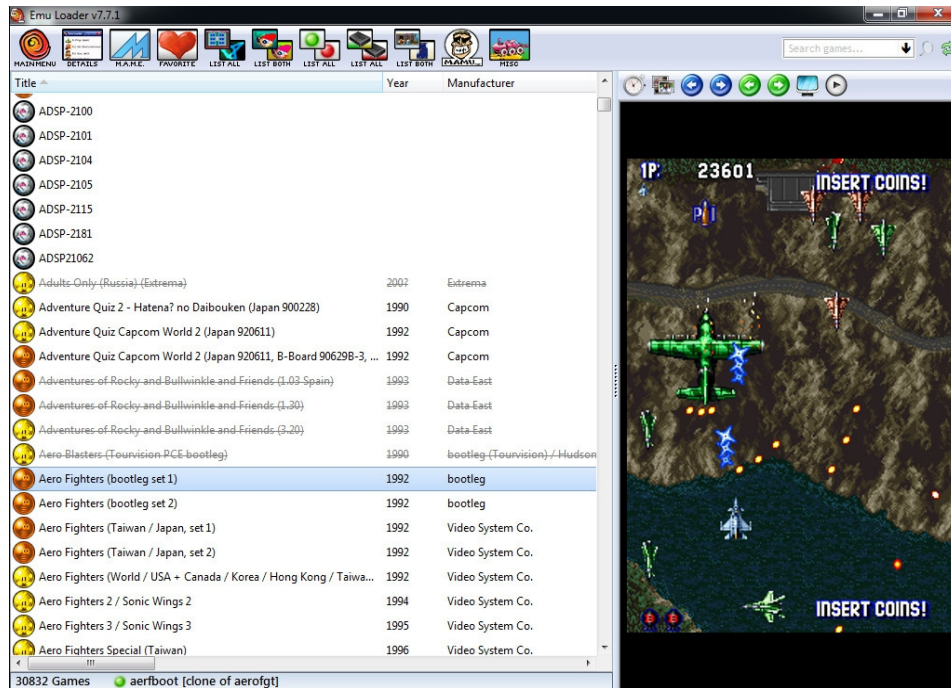

And we see that EmuLoader uses the “mame.ini” file for the settings.

And we test a game with EmuLoader...

.. and it works.

Using the Merger

This function “Merger” I have never used before. I mean how often are you in this situation that you want to change your organisation of the ROMs.

Normally this decision you made at the beginning of collecting ROMs. But anyway I have, for this guide, used the Merger to change my ROMs from a split-set to a merged set.

Let's look how much space it takes with a split-set. Keep also in mind how many files are in this folder

We need CLRMAMEPRO for doing this “Merging”

We choose the V0.158 ROM-dat as our set is at this version.

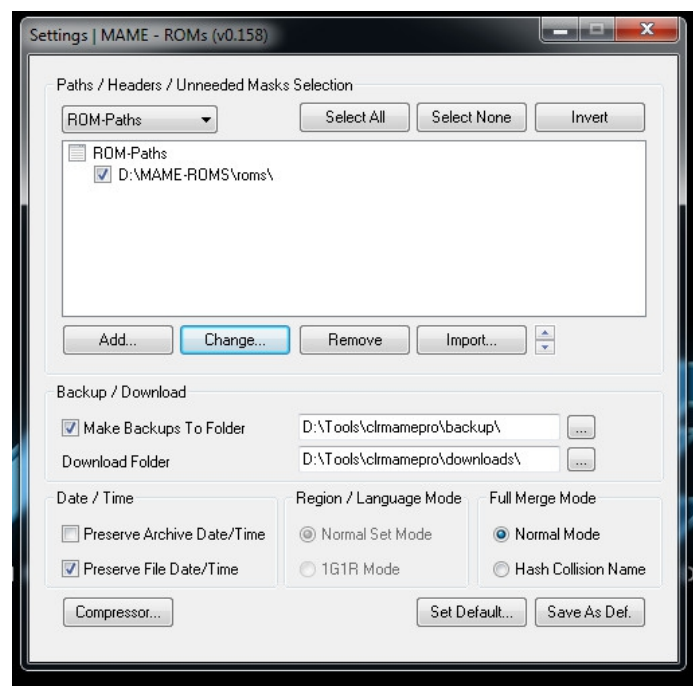

Verify the Settings → ROM-path we have changed in the past.

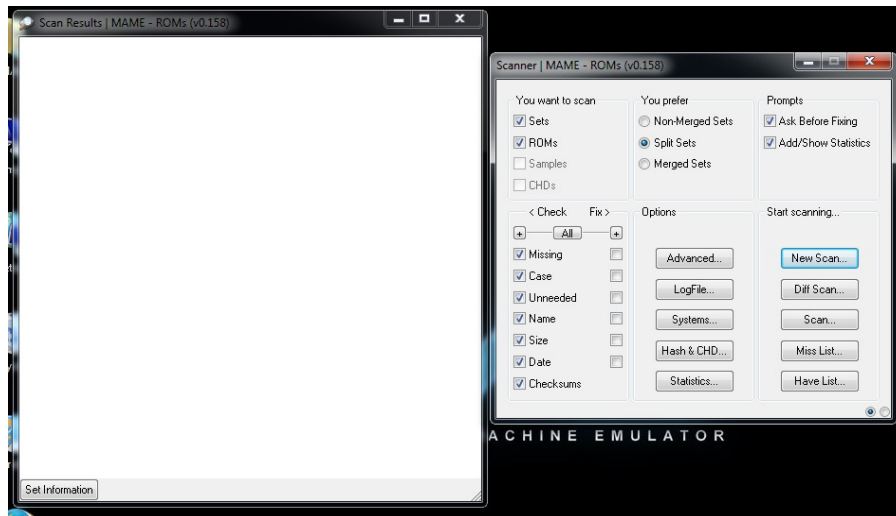

Correct that → we only need the ROM-path and not the CHD-path to add/change → This DAT-file is a ROM only file DAT!

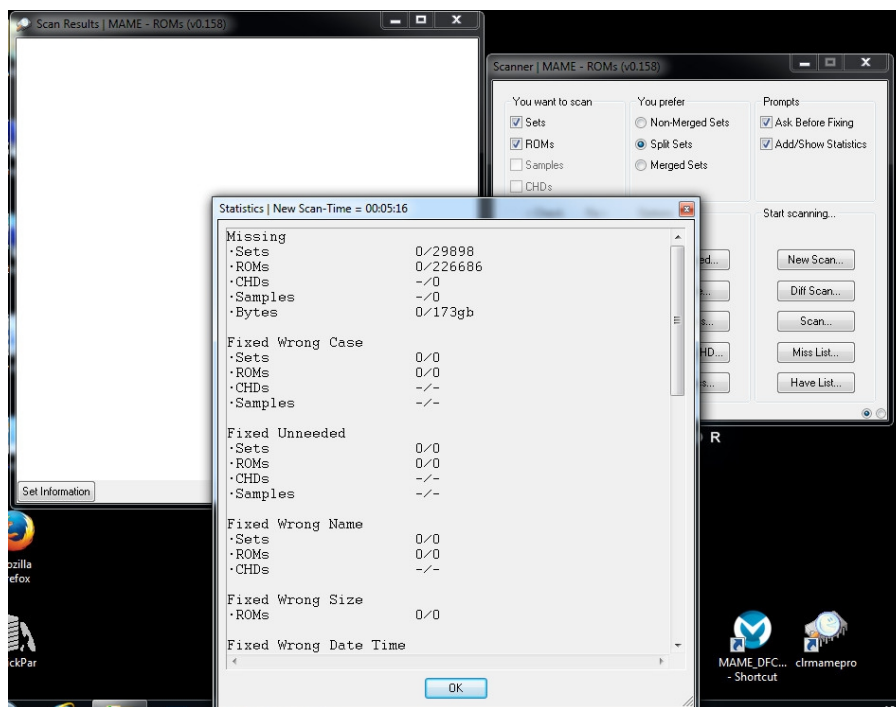

Let's verify first that this set is perfect → with the option “Split sets”

Yeah it is perfect.

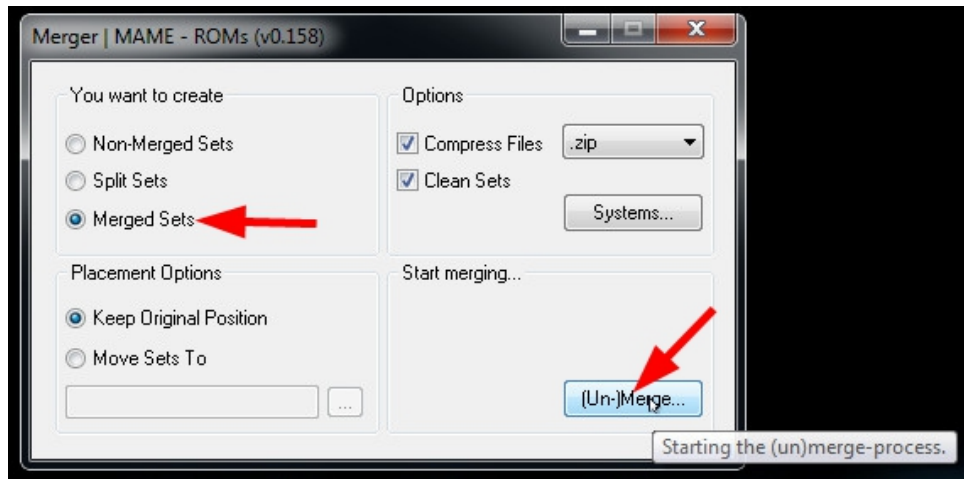

Now start the “Merger”

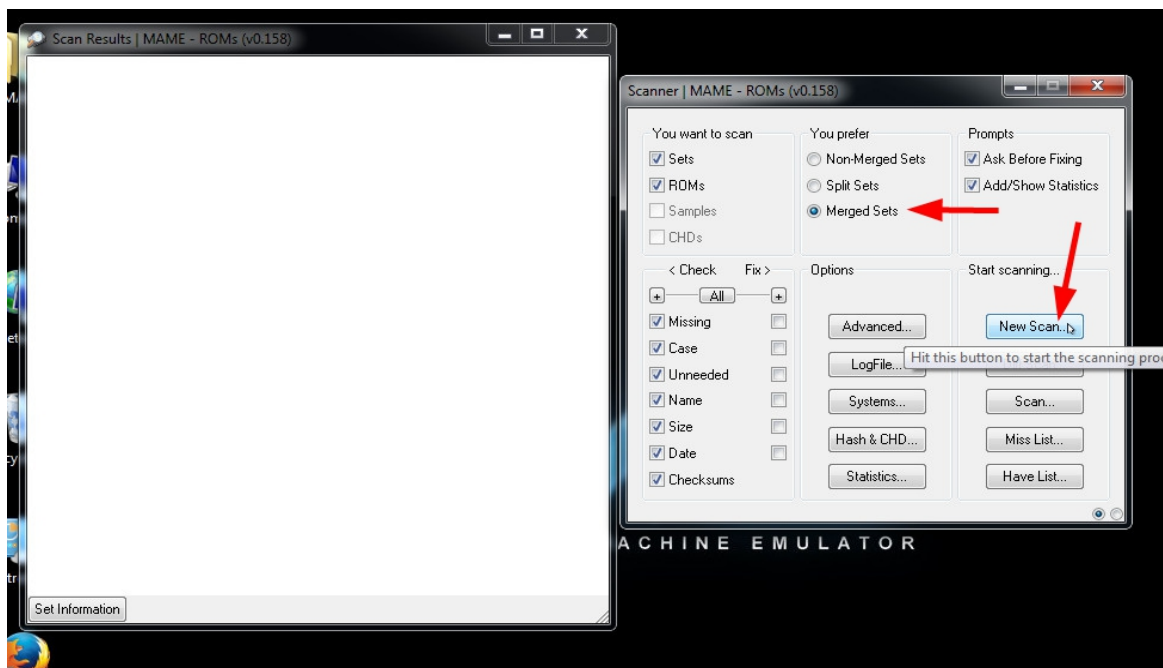

We change the settings to “Merged Sets” and do the rebuilding inside the folder.

After some time it has finished his works and we go back to the scanner.

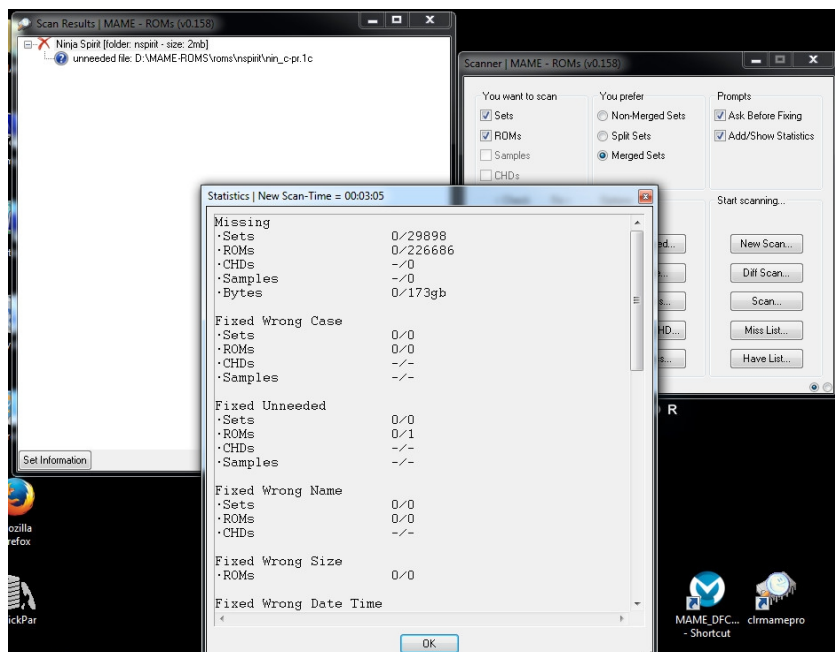

Change the “You prefer” to “Merged sets” and start a “New Scan”

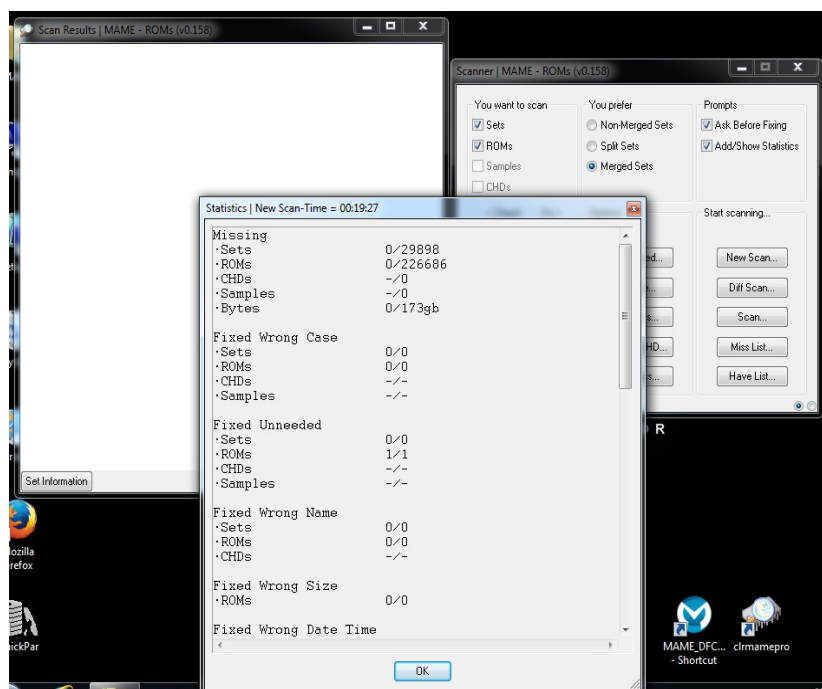

yeah perfecthmm or not perfect ;-)

One ROM is “unneeded”, do a new scan with the fix-option “unneeded” enabled. You should now have a perfect “merged” 0.158 MAME ROM set.

When we look at the folder stats. It takes less space and we see that with this merging “clone” and “parent” into one file that we have massive less files in this folder.

! This was a huge change to your ROM folder. I would suggest that you do it the next time with the “Rebuilder” from the original folder to a new folder (disable “Remove matched sourcefiles”). When everything is perfect you can delete the original folder.

Creating a fix-DAT-file

One of the important function CLRMAMEPRO does provide is creating a “fix-DAT”. When you are looking for missing ROMs and asking for help in forums it is recommended that you upload a fix-DAT for your missings. Nobody will help you when you post topics like that “missing some ROMs for my sets. The are xxx.bin, yyy.bin and sjdsdj.bin”. How can we do that?

Start CLRMAMEPRO

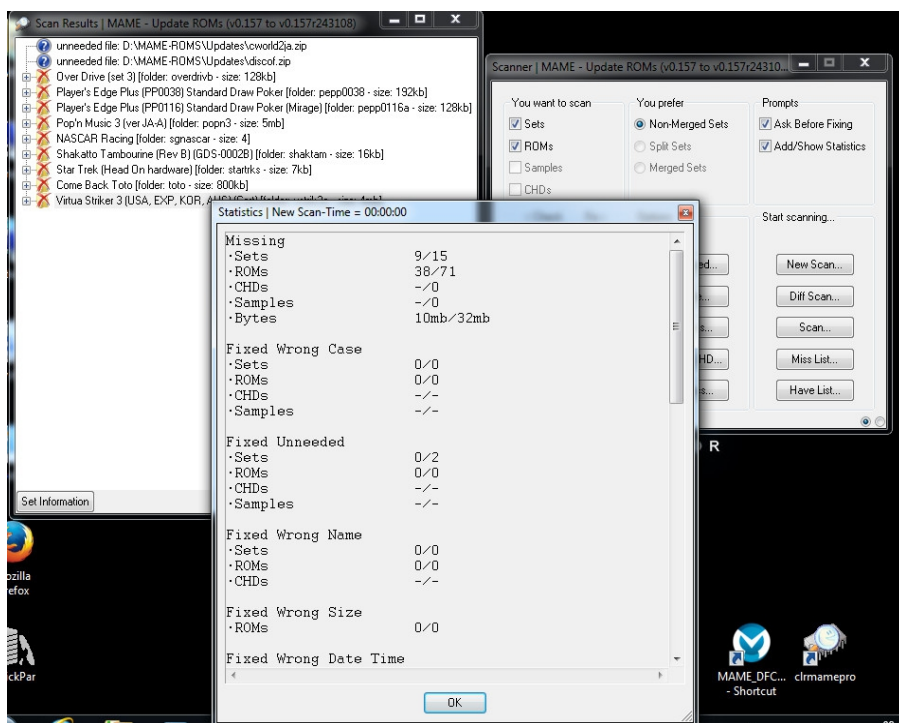

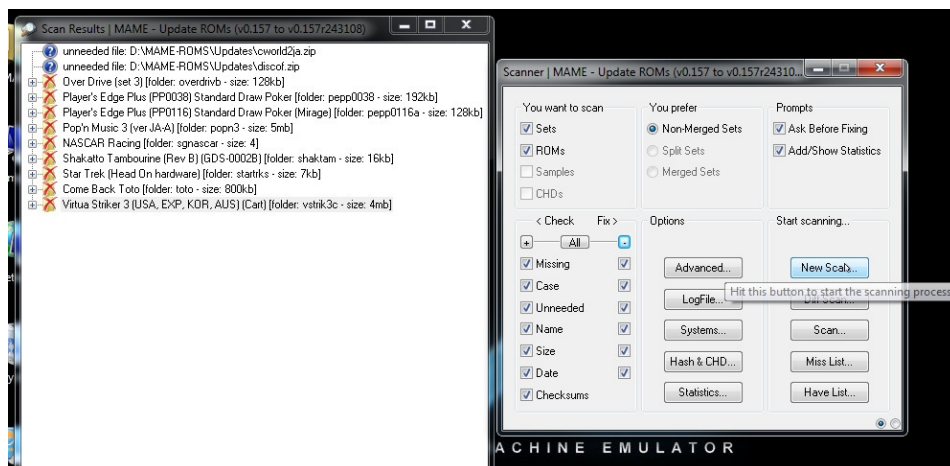

We have a new DAT for our update folder. Add them to CLRNAMEPRO and load it in the profiler.

MAME - ROMs (v0.158)	0.158
MAME - Update ROMs (v0.157 to v0.157r243108)	0.157
MAME 0.157 EXE	0.157 ...

Do a scan with the new DAT on your update folder. We have some ROMs, some are unneeded and we miss 38 ROMs.

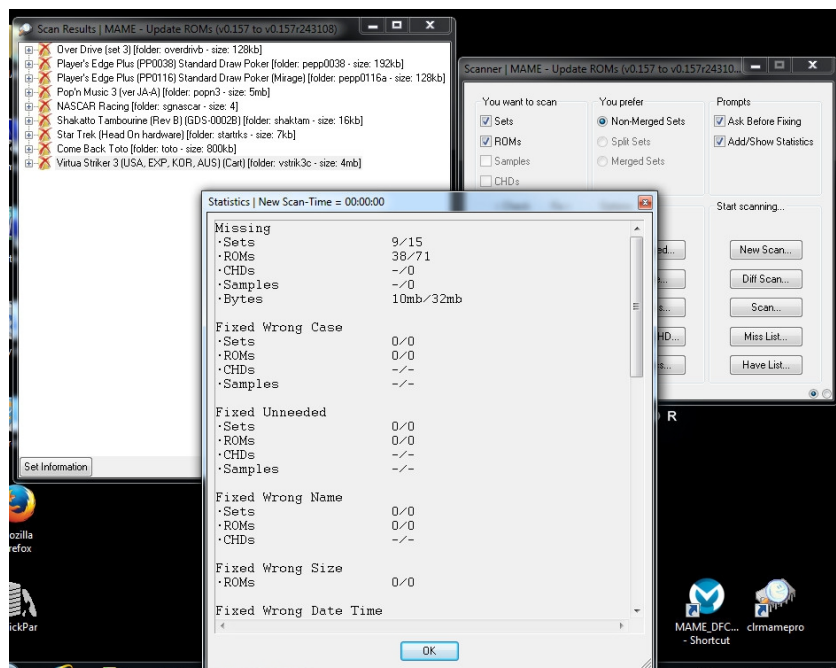

Do a new scan with all available “fix-options” enabled.

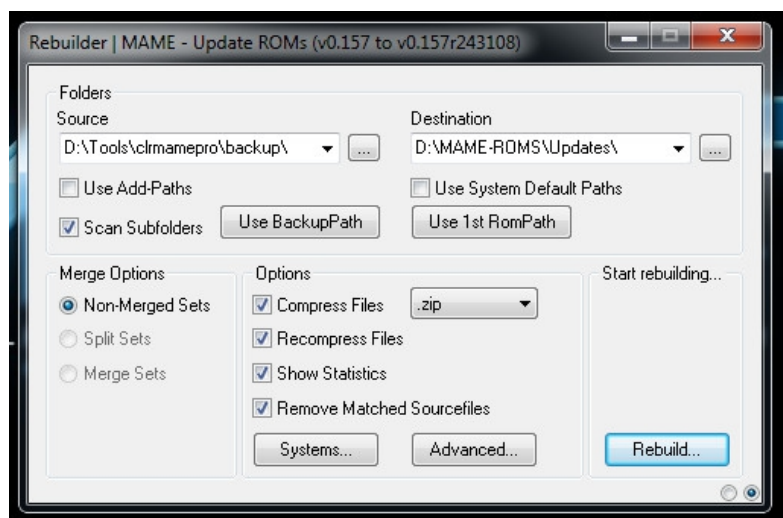

Now we have removed all unneeded stuff from our update-folder.

Before you ask for help you could search for the missing ROMs on your drive. Start the rebuilder

Search for the missing ROMS → Backup-folder → enable “Remove ...”

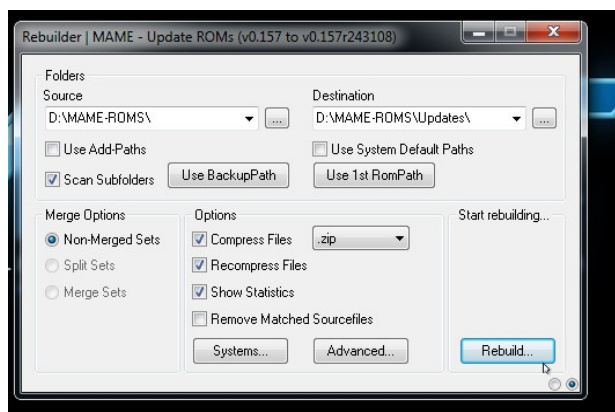

Nothing found

We scan now our other ROM-folders for our missing. Sometimes you have them already but in an other Set or for a another emulator like FBA or Raine. Point the “Source” to your ROM-location, be sure that you disable “Remove Matched Sourcefiles” → you don't want to “corrupt” a folder for a different emulator ...

As our folder is a subfolder of our source folder this “message” pop-up.

While scanning/rebuilding we see that it has found ROMs in an old MAME Set.

37 created files, fine.

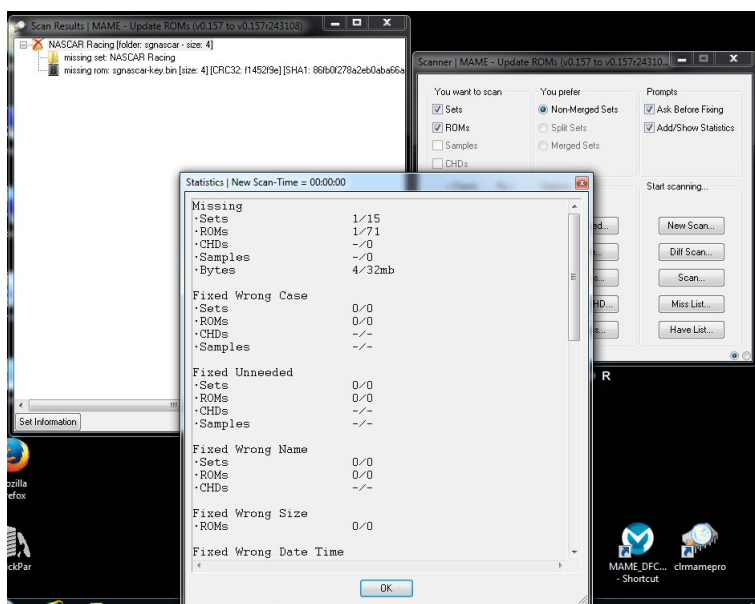

Start a new scan...

Great great we have now only one ROM missing.

It is important that you do this rebuilding for each source-folder that you have. Your fix-DAT will be smaller and that person that helps you save some unneeded upload for nothing.

Now we have everything done and that result we want to save into a fix-DAT. Right-click into the result windows and choose “save - Fix-DatFile - All listed Set Issues”

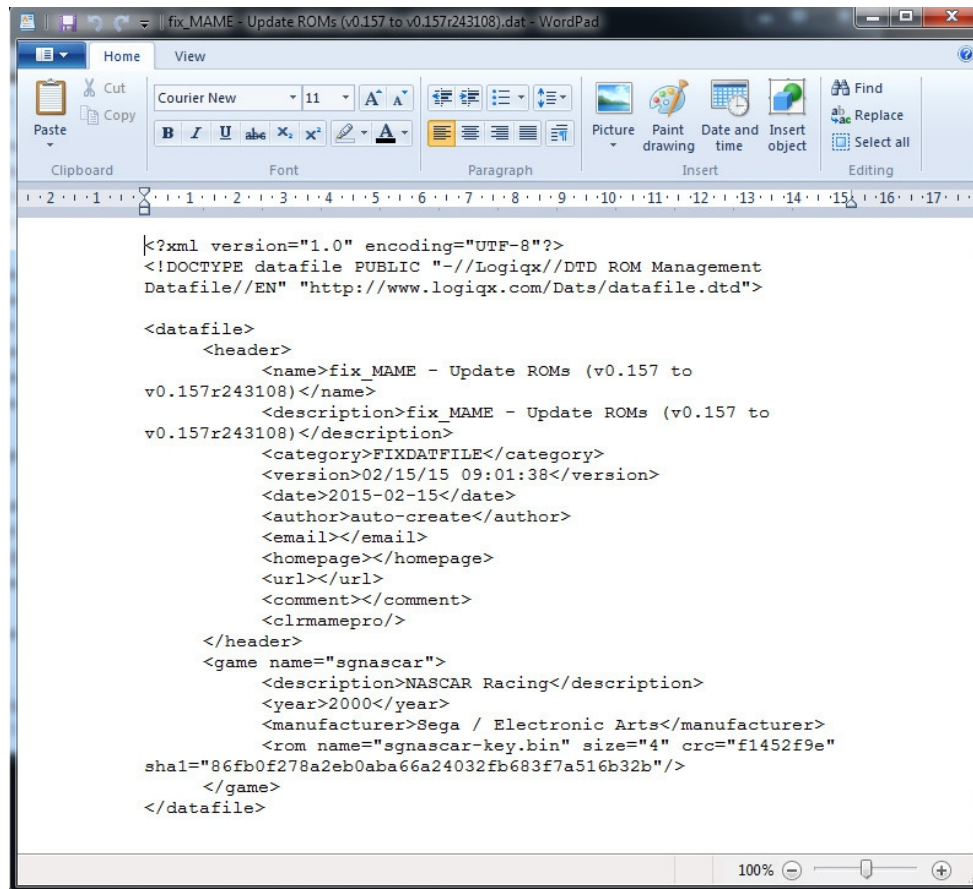

To a folder-path outside your CLRMAMEPRO. You could change the filename but I suggest leave it as it is with this “fix_*” at the beginning.

Open the save fix-DAT with Notepad. You see that only this missing ROM is listed with somedamned there is something wrong, not a real XML-structure ...

Open that file again with Wordpad. Now it looks like it should be ;-)

```
<?xml version="1.0" encoding="UTF-8"?>

```

We have done our first fix-DAT and posted it in a forum. Now I show you what the “other” side will do with your fix-DAT. First load it into the profiler

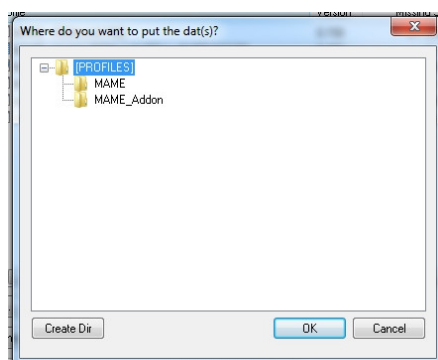

Select the fix-DAT to load.

Place it to the root (or create a subfolder for that).

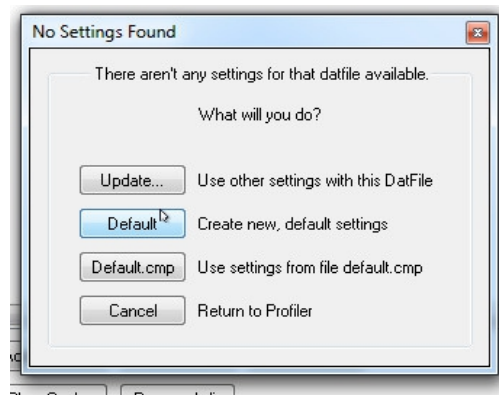

And load it into the profiler

Choose “Default”

Go to the “Settings”

Set the ROM-path to a new temporary created folder. After we have send the ROMs for this fix-DAT we delete this folder.

Now we scan for this missing ROMs and rebuild it to our temp folder.

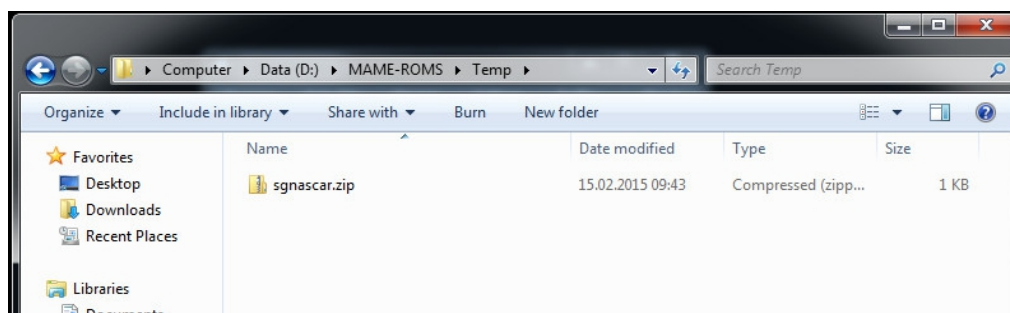

! The option “Remove Matched Sourcefile” is greyed out and can not be activated → This option is disabled when using a fixdatfile (Look at the XML → Category “Fixdatfiles”)

We have found the missing file in our source folder.

Yeah it is in our temp folder

We can now delete this “fix-DAT” from our profiler as we don't need it for our set ;-)

We have posted or sent that file to the one that has requested it. We switch now back to our set as we miss this file ;-)

Load the DAT-file for that set you have created this fix-DAT into the profiler.

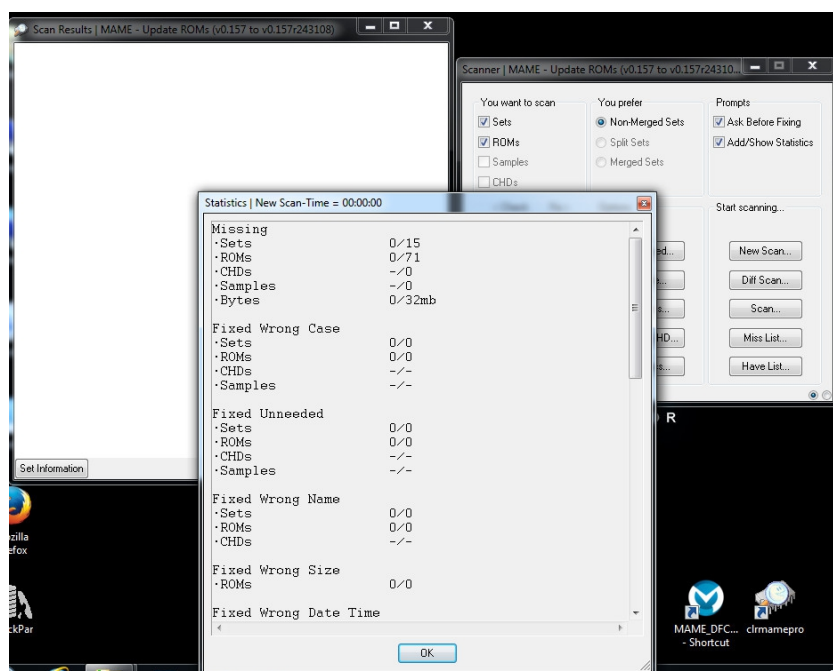

! As we are the person that is missing ROMs and has created a fix-DAT for others to help we don't need that fix-DAT ourself. Load the original DAT file and do a rebuilding with the files you have received.

The received ROMs we store on a temp folder. We set the source in the rebuilder to that temp folder and do a rebuilding. As this is not a fix-DAT we can enable “Remove Matched Sourcefiles”.

After a scan we see that we have now a complete update set.

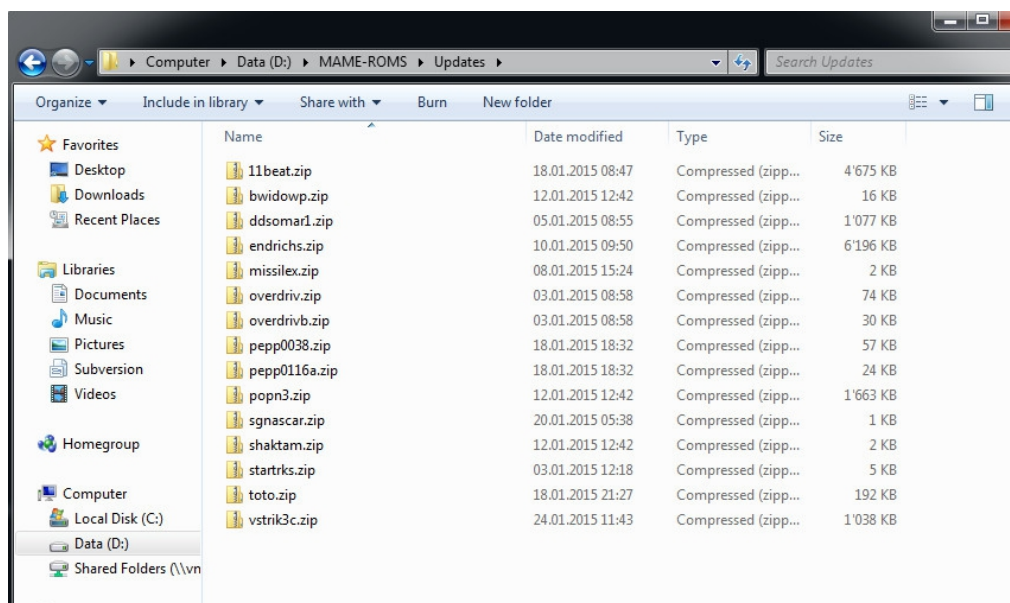

! Please note that this “fix-DAT” option is a way to help others as well and receiving help. That's the reason that I have showed you both sides :-)

Creating a DAT-file with Dir2Dat

CLRMAMEPRO can create DAT-files from a folder-structure. Why do we need to create a DAT-file? I can create it from an executable or download it from the Internet to scan my set! This option is only used for stuff that you want to share and provide for that a DAT-file. I have used that option for my titles-snapshots to provide a DAT-file to others for scanning and rebuilding “my” set. I will show you how you can create a DAT-file with “Dir2Dat”.

We have some special ROMS in our Update-folder and we want to provide them to othersand creating a DAT-File for that :-)

Start the engine CLRMAMEPRO

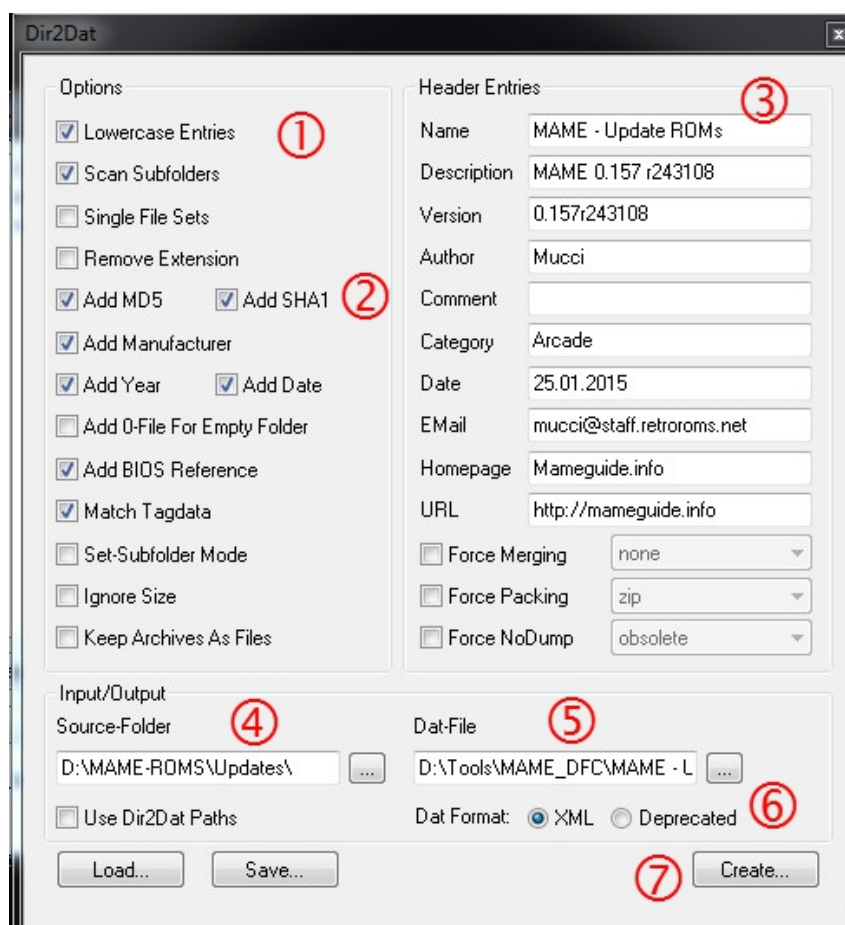

In the profiler we do not load a DAT-file, click “Dir2Dat”

We must fill in some information ...

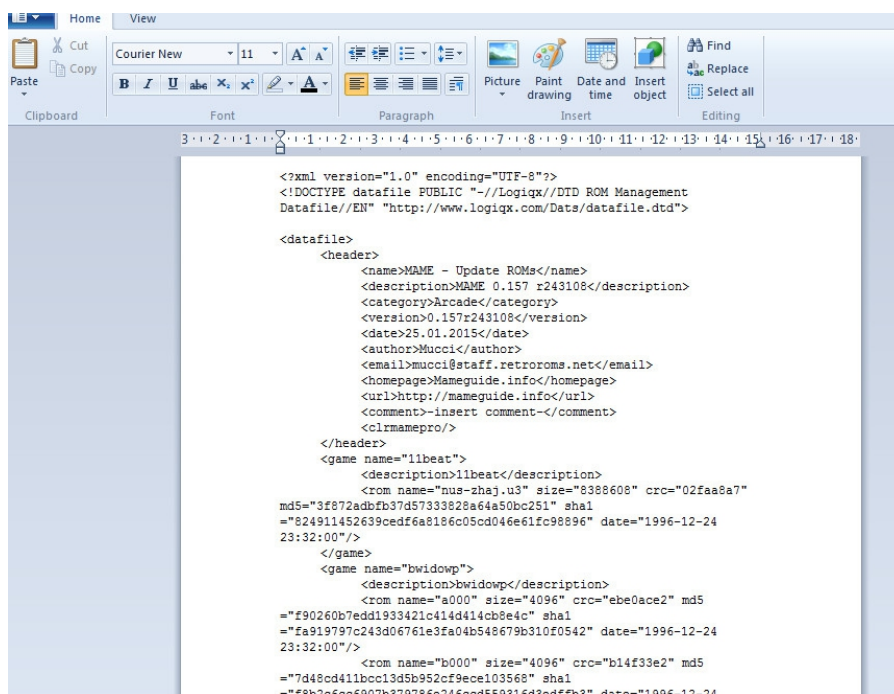

- ① In this Option you can specify what should be included in the XML-file.
- ② This Options define which hash-code you want to have in the XML-file
- ③ In this “Header” section are information that are available in your XML-file. It is used for the ROM-manager to display this information.
- ④ In the “Source-Folder” you are pointing it to the folder you have your files and want to create the DAT-file for
- ⑤ The destination where the DAT-file should be created
- ⑥ DAT format: Use XML when possible, all new ROM-Manager supports it.
- ⑦ Create-Button → starts the process

After the DAT-file is created it displays this message

If we open that DAT-file with WordPad we see that all the information we have entered:

```
<?xml version="1.0" encoding="UTF-8"?>

```

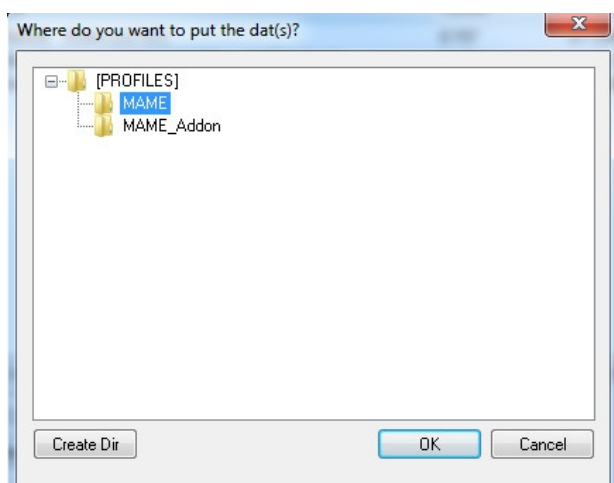

We have created the DAT-file and someone else uses it to verify that he has the same set of ROMs. Add the DAT-file into the profiler.

Choose the DAT-file.

We store it in the “MAME” folder.

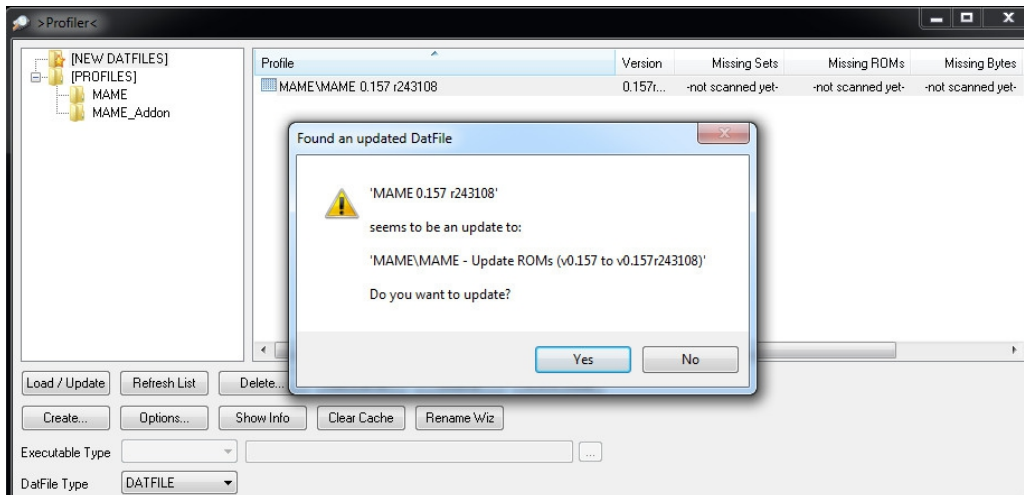

Load the DAT-file

This message appears. Why? Because we have set the name “MAME - Update ROMs” in the Header section. This is the default also DFC uses. That's why CLRMAMEPRO shows you this “update” suggestion. Click “no”

Click “Default”

Go to the “Settings”

Set the ROM-Paths to your folder that holds that update ROMs.

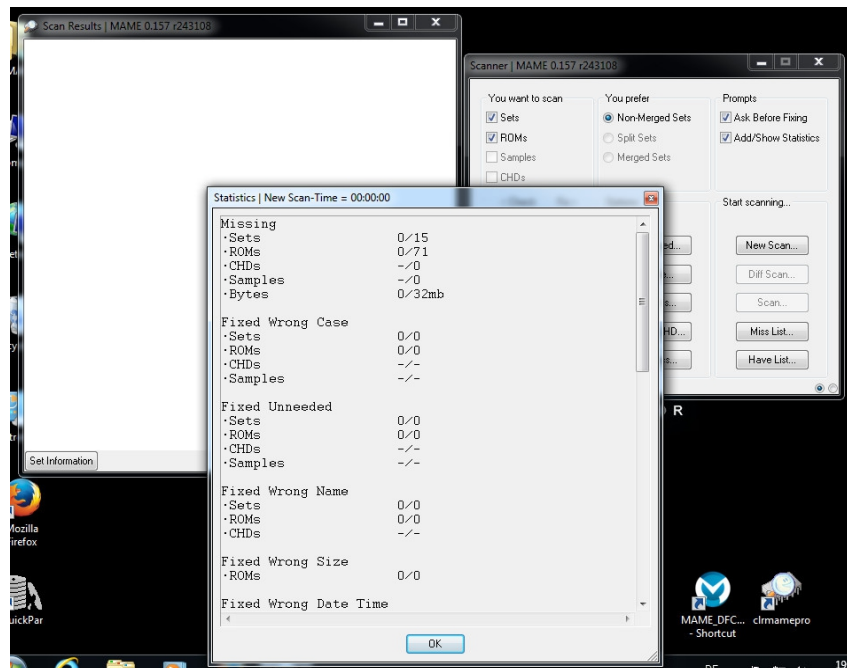

Go to the scanner and check what is available under “Hash & CHD”. We have created the DAT-files and have enabled MD5 and SHA1. We see now that we can choose it for verifying our ROMs.

After the scan it shows us the report.

Using Batch-Mode

We have used CLRMAMEPRO for scanning/rebuilding one set at a time. But CLRMAMEPRO has more power inside it is called “batch-mode”. When you are looking at those softwarelist for MESS. Can you remember where the DATs are (xml)? Right they are under “D:\Mess\hash” and yes they are over 300. You now have two choices add 1 DAT, scan and rebuild it, add the next DAT and after some days of hard work you have reached hopefully the end ;-)

The other way is that we can automate that with CLRMAMEPRO.

Let's look first at our Softwarelists folder:

We have only a few there and we want that set complete.

We have our MESS emulator updated to V.0158

And in this hash folder are all DAT-files in a XML-format available.

We start CLRMAMEPRO

In the profiler we click on “Add DatFile”

We change the folder-path to “d:\Mess\hash” and select all available XML-file (Ctrl+A). Click “Open”

! In our example we do not separate SL ROMs (Softwarelists) and SL CHDs. All SL CHDs together needs 1.5TB and some torrent sites make for that reason two torrents for this SL: One for the ROMs and one for CHDs (check there if they have separated the DAT-files and use them)

Some XML does not represents ROMS, like iq128.xml and vreader.xml. They could be reported as an error within a ROM-Manager.

We are choosing all available XML and we will see what happens ;-)

Click “Create Dir” (at the root of the Profiles)

Enter the name of the folder to be created in profiles. This have to be the same name as the folder name where you want/have to store the files!

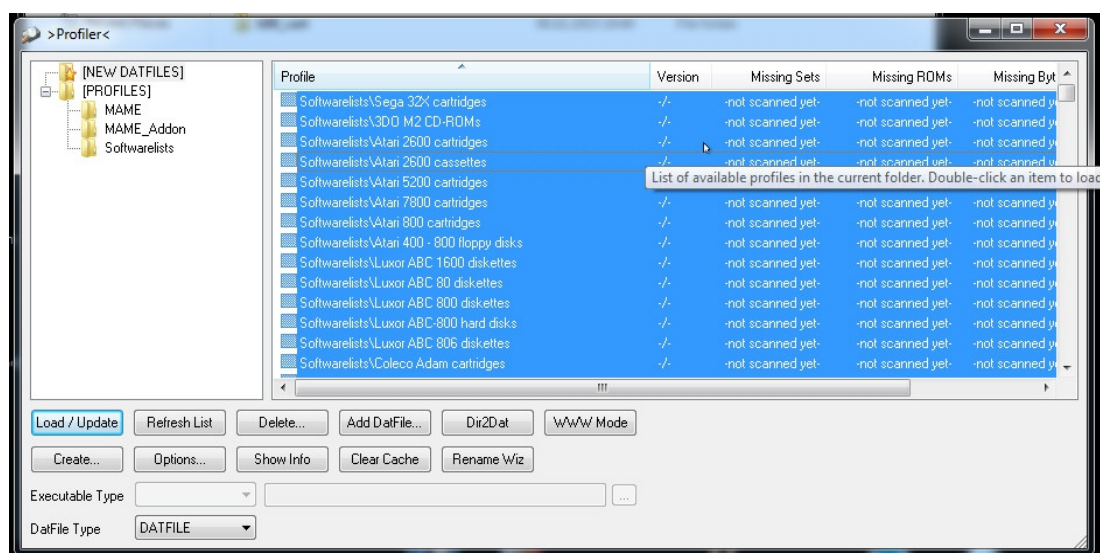

Click “OK” for the folder creation and “OK” for choosing it.

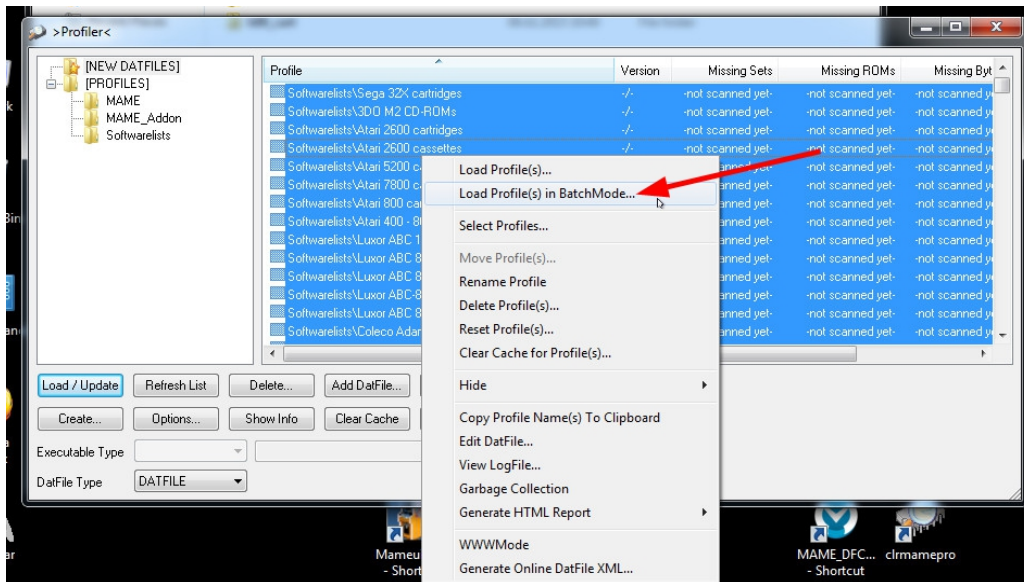

Now we have all DAT files under “NEW DATFILES”. Select all with “CTRL +A”

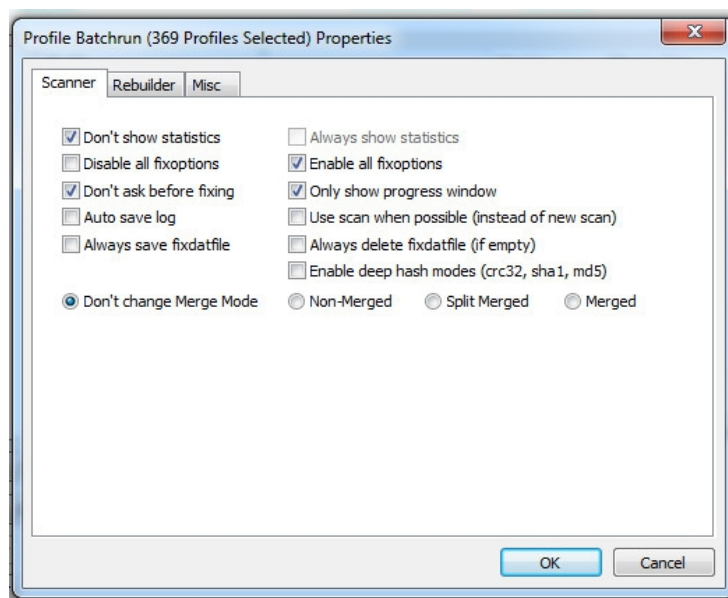

Now do a right-click and choose “Load Profile(s) in BatchMode” from the context-menu.

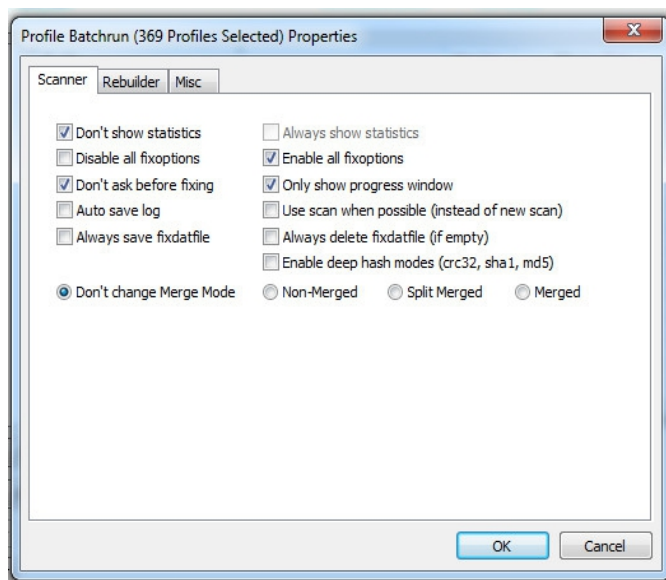

A new window appears called “Profile Batchrun (x Profiles selected)...”

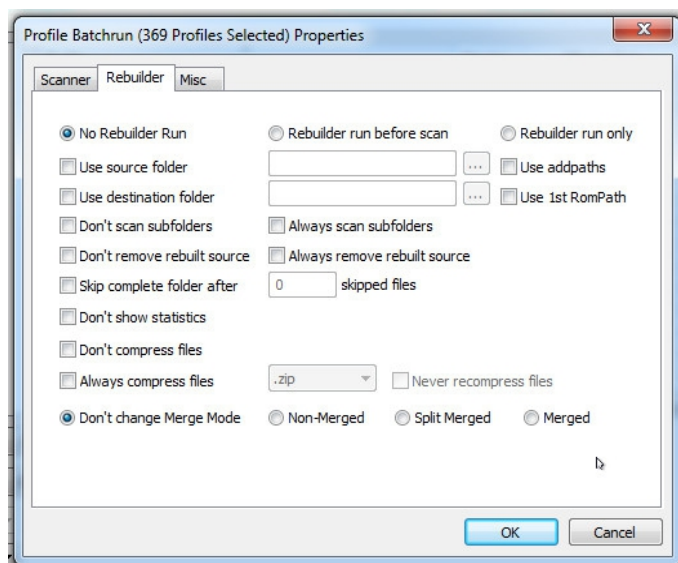

In this windows we have three tabs: Scanner, Rebuilder and Misc. Let's explain each.

In the Scanner tab you can choose all the settings that are being used for scanning. I have enabled “Don't show statistics” as I don't want to click over 300 times “ok” on the statistic report window. “Enable all fixoptions” should be enabled as well.

The tab “Rebuilder” we do not need for the first scan. We do need it later. Be sure that you have chosen here “No Rebuilder Run”

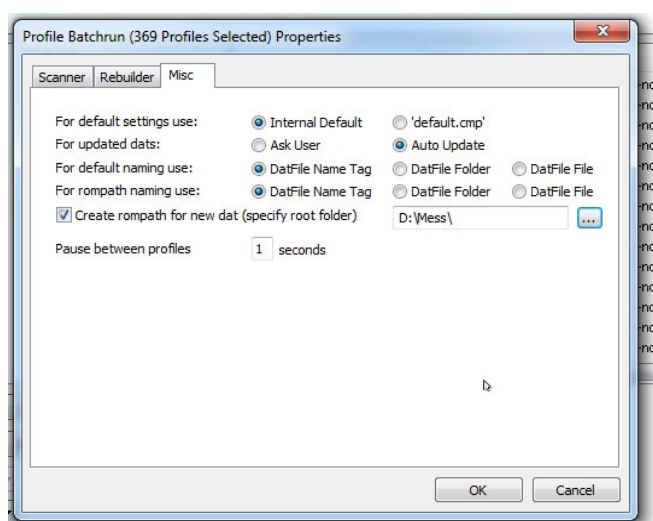

The last tab is called “misc”. We enable “create rompath for new DAT...” and choose the folder where your Softwarelists are. Be sure that you are NOT choosing the “D:\Mess\Softwarelists” → select the upper folder → “D:\Mess “

Don't worry it will scan below this “D:\Mess\Softwarelists” ;-)

Set the Pause between profiles to 1 second.

We can now scan in batch-mode for the first time. This first should always be started without “Rebuilder” enabled, be sure that you don't have enabled it before you click “OK”.

When the batch-mode scan change to the next DAT-file you can see the status where it is.

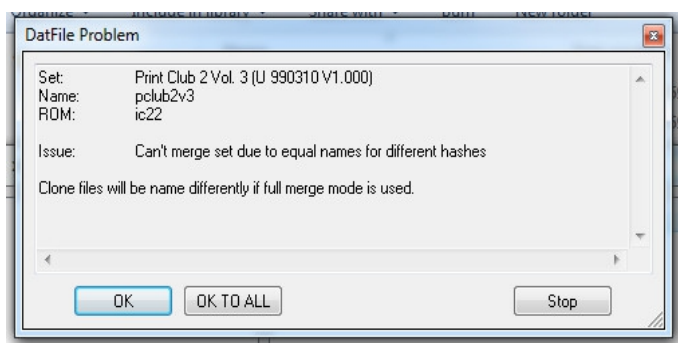

Same as in the normal scan process you could be asked for a decision when there is a conflict. Choose “OK to all”

Same here, click “OK to all”

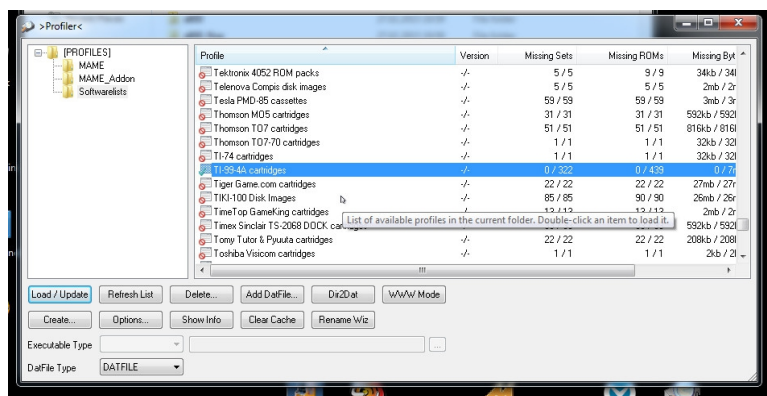

After a while we do get this error message:

The batch-mode has stopped. I have mentioned earlier that this DAT-File “vreader.xml” has no ROM information inside and CLRMAME does not like it and show this stop message. Click “OK” and start the batch-mode scan again with the rest of the DAT-Files that are under “NEW DATFILES”.

After the scan has finished you will see in profiler that we have a lot of missing. Yeah we have only a few added some time ago for testing MESS.

The screenshot shows a Windows Explorer window with the address bar displaying the path: Computer > Data (D:) > Mess > Softwarelists > c64_flop. The search bar contains the text 'Search c64_flop'. The left sidebar shows the 'Favorites' section with links to Desktop, Downloads, and Recent Places, and the 'Libraries' section with a link to Documents. The main pane shows a table with columns: Name, Date modified, Type, and Size. The message 'This folder is empty.' is displayed in the center of the main pane.

The screenshot shows the Profiler application interface. On the left, a tree view shows the file structure: [PROFILES], MAME, MAME_Addon, and Softwarelists. The main window displays a table of files with columns: Profile, Version, Missing Sets, Missing ROMs, Missing Bytes, and Timestamp. A dialog box titled "DatFile Information" is open, showing details for the selected file "vreader.dat".

Profiler Main Window Table:

DatFile Information Dialog:

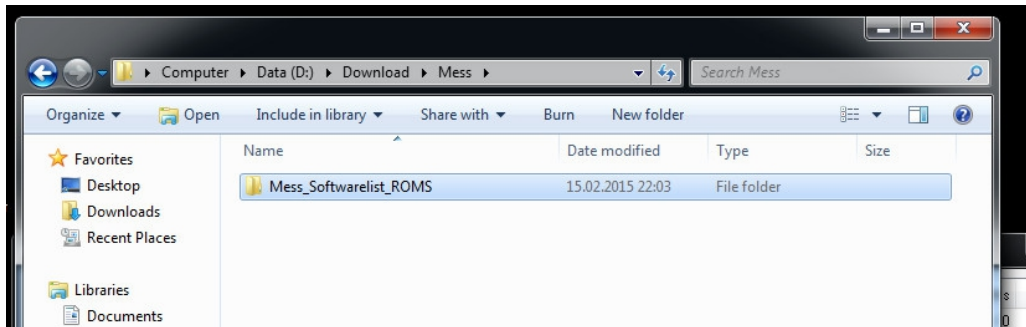

DatFile / Profile Information

Name	vreader	Date	-not specified-
Author	-not specified-	URL	-not specified-
Version	-not specified-	Homepage	-not specified-
Description	VTech V.Reader - Storio cartridg	Email	-not specified-
Comment	-not specified-	Last Used	02/27/15 20:19:06
DatFile Name	Softwarelists\vreader.dat		

At the bottom of the Profiler window, there are buttons: Load / Update, Refresh List, Delete..., Add DatFile..., Dir2Dat, and WWW Mode.

We have downloaded SL-ROMs from the Internet to our download-folder.

In the profiler choose all available profiles in the Softwarelists (CTRL + A).

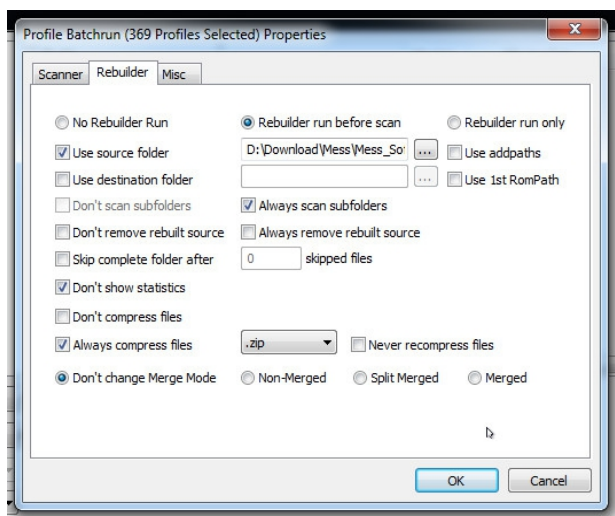

Do a right-click and load them into the batch-Mode

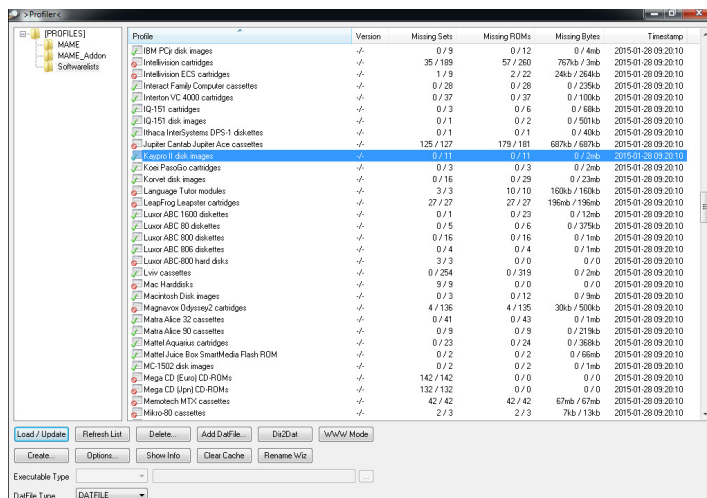

In the Batchrun window we leave the scanner tab as it is and enable “Rebuilder run before scan” in the “Rebuilder” tab. Activate “Use source folder” and point it to your download-folder. Also here it is recommended that you enable “Don't show statistics”. The rebuild ROMs should be stored inside a zip-file → Enable “Always compress files” and choose zip-file. Start the process with “OK”....

The rebuilding and scan of all this profiles takes a while. After it has finished the profiles should shows now a better statistics which profile is complete or has missing sets.

Now you should have more files inside those folder ;-)

As I have not a complete set myself (It was an older SL-Set) you can now search for the missing sets yourself. Load only 1 set into the profiler, scan, rebuild and create a fix-DAT for the missing. Or use the batch-mode to perform more than 1 profile automated. By the way there is an option in the “Scanner” tab for saving a fixdat for uncompleted profiles, activate that and all fixdat are saved in the CLRMAMEPRO folder “fixdats”.

Now we have completed our SL and a new MESS is published. We have updated our emulator to V.0159 and it has new or changed SL-Lists ..

```
C:\Windows\system32\cmd.exe

D:\Mess>mess64.exe -?
M.E.S.S. v0.159 (Feb 25 2015) - Multi Emulator Super System
Copyright the MESS team

MESS is based on MAME Source code
Copyright Nicola Salmoria and the MAME team

MESS is an emulator: it reproduces, more or less faithfully, the behaviour of
several computer and console systems. But hardware is useless without software
so a file dump of the ROM, cartridges, discs, and cassettes which run on that
hardware is required. Such files, like any other commercial software, are
copyrighted material and it is therefore illegal to use them if you don't own
the original media from which the files are derived. Needless to say, these
files are not distributed together with MESS. Distribution of MESS together
with these files is a violation of copyright law and should be promptly
reported to the authors so that appropriate legal action can be taken.

Usage: MESS [system] [media] [software] [options]

    MESS -showusage      for a brief list of options
    MESS -showconfig     for a list of configuration options
    MESS -listmedia      for a full list of supported media
    MESS -createconfig   to create a mess.ini

For usage instructions, please consult the files config.txt and windows.txt.

D:\Mess>
```

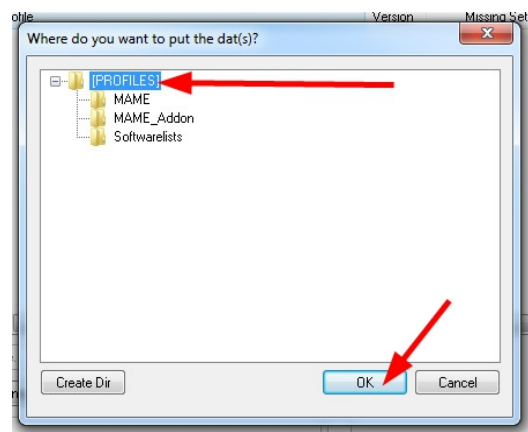

Start CLRMAMEPRO and click “Add DatFile” in the profiler.

Again choose all XML-File from the hash-folder (D:\Mess\hash)

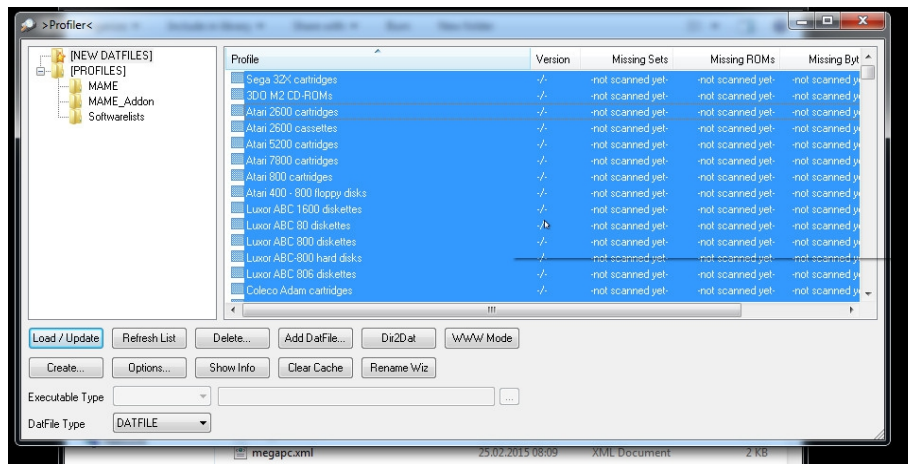

After you have clicked “OK” choose the Profiler root folder as your destination (and not “Softwarelists”).

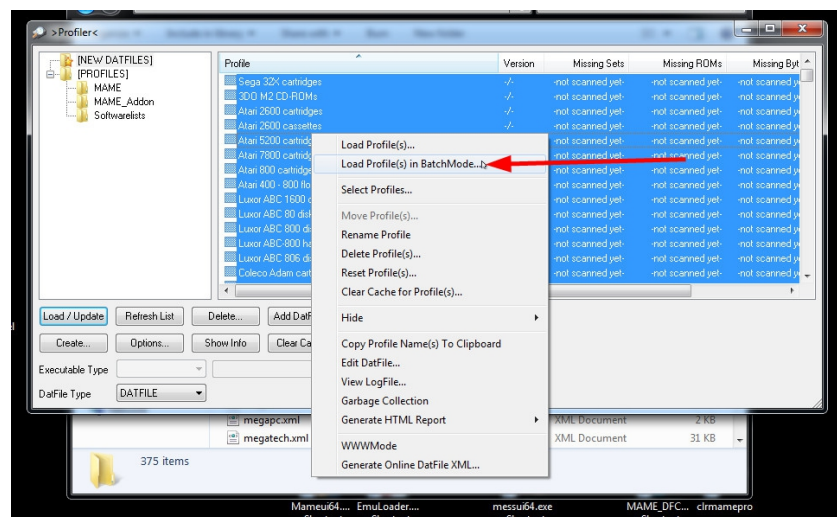

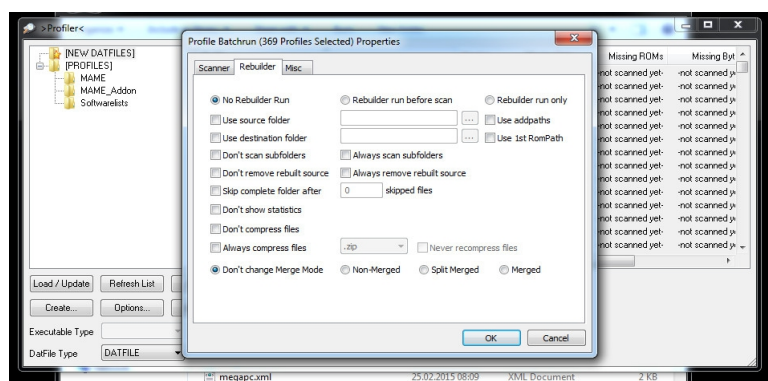

Choose all SL-Profile in the profiler that are under “NEW DATFILES”.

Do a right-click and choose “Load Profile(s) in BatchMode”

And again do the first run without “Rebuilding”. There are maybe new SL-Sets added and their directory has to be created first. Disable “Rebuilder”

Check all the other settings in the tab “Scanner” and “Misc” to be sure that they are correct before starting the process with “OK”.

! You are wondering why we have stored this DAT file under the root and not under Softwarelists? The reason is simple CLRMAMEPRO does detect that you have a same DAT-File already in your DAT-Folder and replace it with the new one.

Again after a while we have this error from the “vreader.xml”

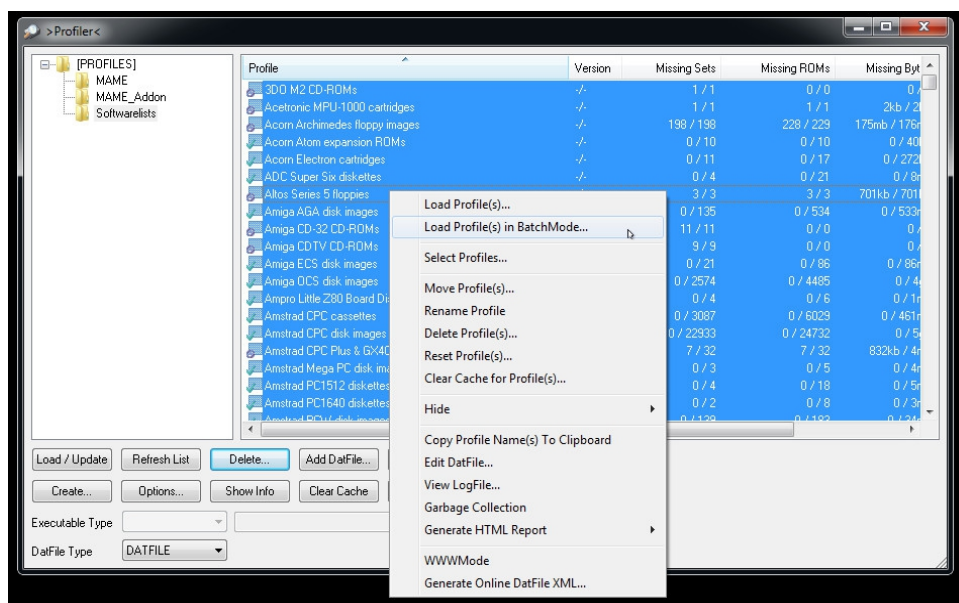

Click “OK” and do another Batch run with the rest of the SL-DATs in under “NEW DATFILES”. (And again DO NOT enable “Rebuilder” ;-))

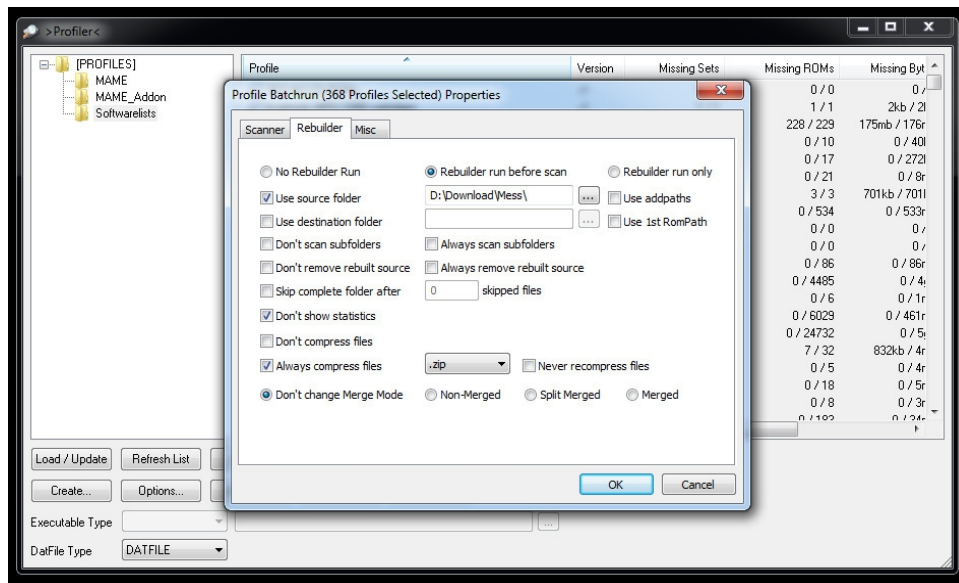

We have now updated our Softwarelists with the new SL-list from MESS.

Load them all again into the “BatchMode”

And activate now the “Rebuilder” and point it to a folder where you have downloaded new ROMs.

We have now our Softwarelists for MESS again complete.

! Remember: Rebuilder does not rebuild CHDs files. You have to move/copy them manually to the destination folder!

Creating a set for an older MAME version

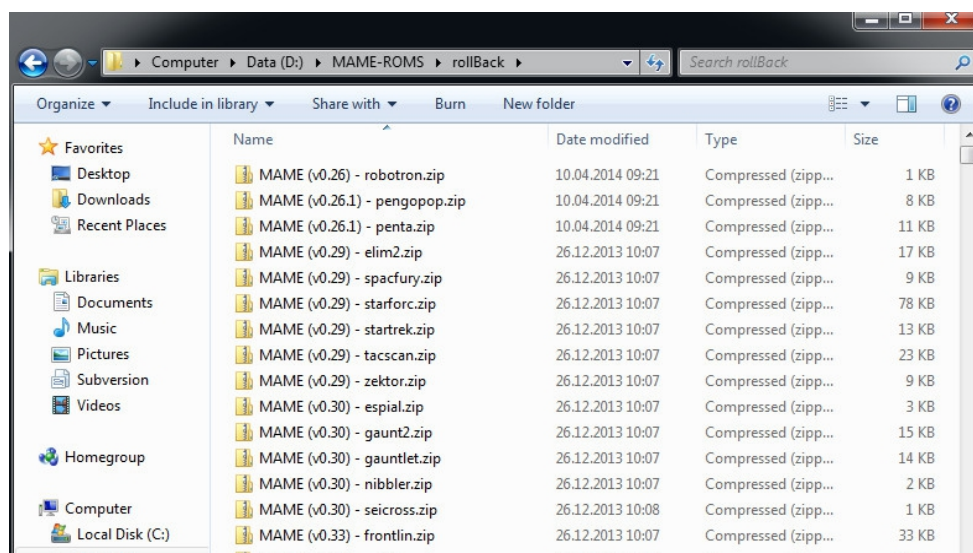

Normally you should not go back to an older version of MAME. Each new version of MAME does brings better emulation and eliminates errors. But there is a reason why you have to use an old set. For example in your “MAME Cabinet” is an old PC or you want to play it on a tablet/mobile that have not enough power to start the latest emulator (or it is not available for that model).

In our example we want to create a set for MAME Version 0.139.

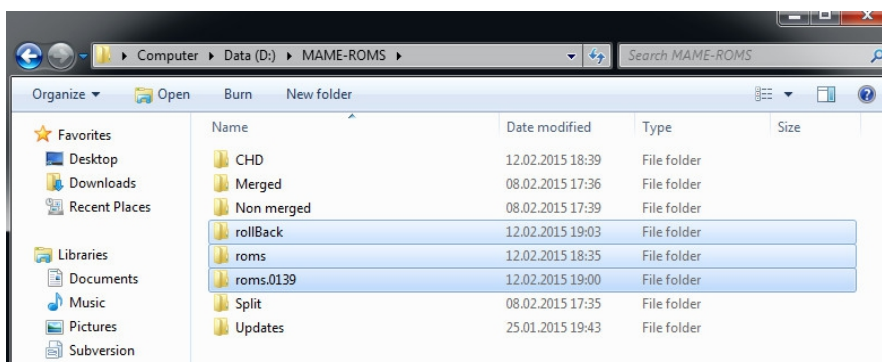

Create a folder in our MAME-ROMs folder called “roms.0139”

For going back in the version you might be need some files that have been removed or updated in a later set. There are download-sets available in the Internet that are called “MAME rollback set”. To have a perfect set for 0.139 you will have to need that as well. I have downloaded them in a separate folder called “rollBack”

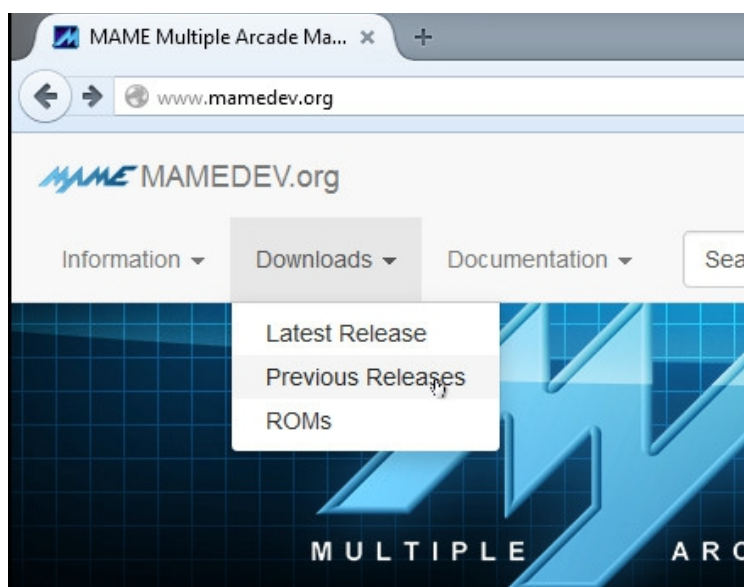

For rebuilding an old set you will need to have this three folders.

- rollBack: All removed old sets
- roms: That is the folder where your latest MAME ROMs are
- roms.0139: empty folder that we use for rebuild into it

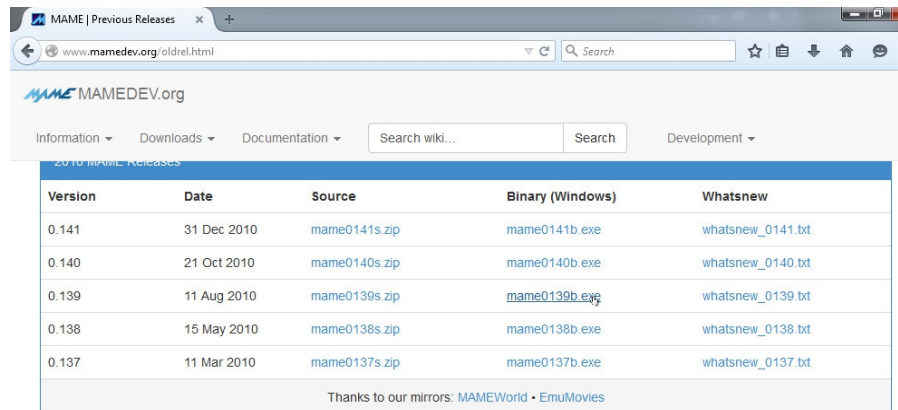

The first step is that we need a DAT-file for the V0.139 ROMS. If you have not such a DAT-File we can use an executable to have this information available. Open a web-browser and navigate to MAMEDEV and choose there “Downloads - Previous Releases”.

Scroll down and find the 0.139 executable.

MAME/MESS The Guide

Version	Date	Source	Binary (Windows)	Whatsnew
0.141	31 Dec 2010	mame0141s.zip	mame0141b.exe	whatsnew_0141.txt
0.140	21 Oct 2010	mame0140s.zip	mame0140b.exe	whatsnew_0140.txt
0.139	11 Aug 2010	mame0139s.zip	mame0139b.exe	whatsnew_0139.txt
0.138	15 May 2010	mame0138s.zip	mame0138b.exe	whatsnew_0138.txt
0.137	11 Mar 2010	mame0137s.zip	mame0137b.exe	whatsnew_0137.txt

Thanks to our mirrors: MAMEWorld • EmuMovies

! MAMEDEV does only provide official releases. When you need an executable for example for V0.139u1 you have to search somewhere else!

Download it to your download-folder

Starts it and extract it to a separate folder (not the ROM-folder)

We have now the executable in that folder :-)

We start a command-line window and create the ini-file first with “mame.exe -cc”. We are doing this only because we want to test MAME 0.139 after we have rebuild the ROMs.

Start a second commando “mame.exe -listxml >mame-0139.xml”. That creates a XML-file (DAT) and safe it to a file that we can use in CLRMAMEPRO.

Start CLRMAMEPRO

Click “Add DatFile” in the profiler

And load our XML-File that we have created

Place it in the “MAME” folder.

Load that created profile.

Use the “default” settings

We have some conflict during the load of the DAT-file. Click “OK to all”

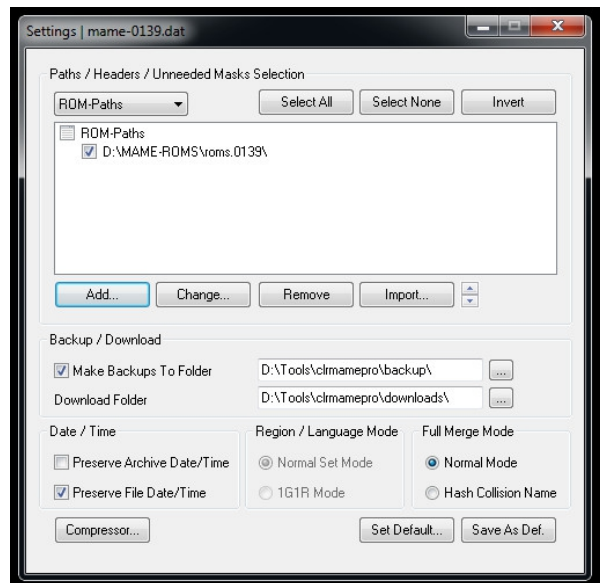

Go into the settings

And set the ROM-path to the empty 0.139 folder.

And add the Sample-Path to a new folder. You can create it with the “add” dialog.

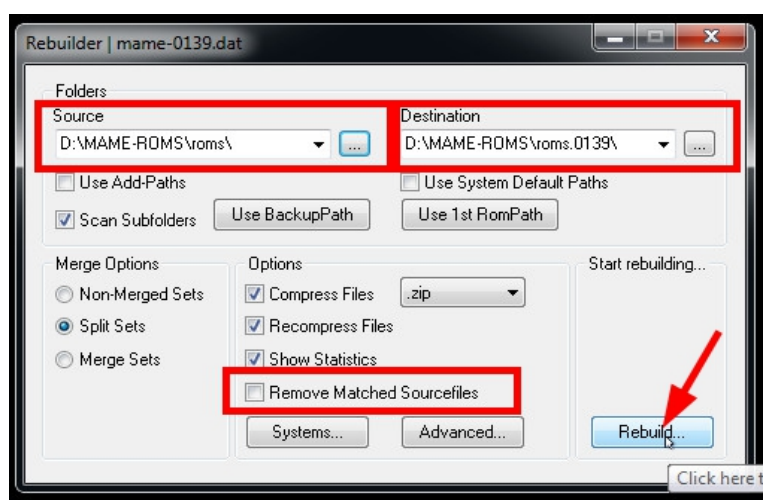

Just checking the file-system :-)

Close the setting window and we use now the rebuilder (scanning makes no sense because those two folder are empty).

Point the source to your MAME-ROMs folder. Do NOT enable “Remove Matched Sourcefiles” as they would be missing in your latest Set.

After the rebuild we are doing a scan to see what the status is.

Hmm not perfect ...

Going back to the rebuilder.

Do a second rebuild from the rollback folder (source)

And indeed it does rebuild from the rollback folder....

Statistic says 414 createdhmm we had 414 missing

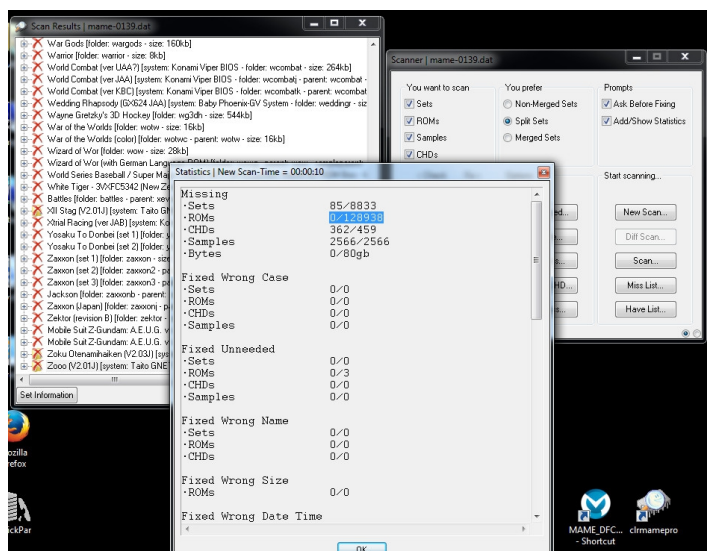

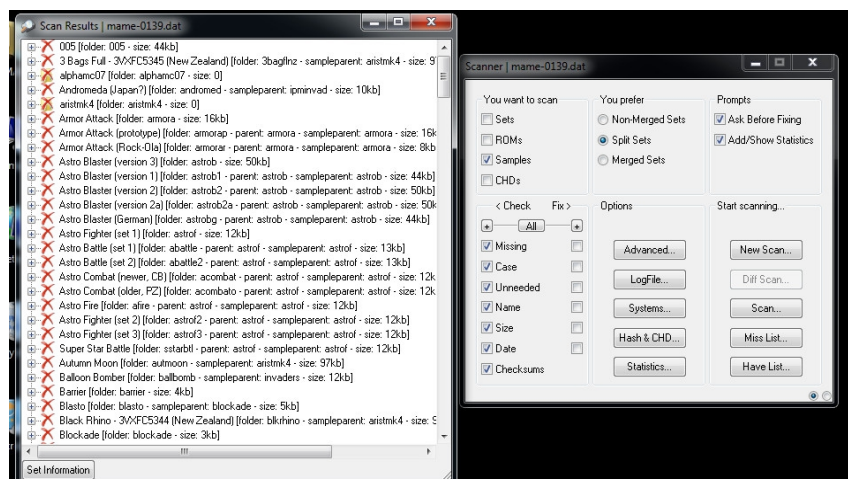

Hurry hurry do a new scan :-)

Yes we have 0 missing ROMs. We have now only missing Samples and CHDs.

When you do a scan only with “samples” activated you see which one are missing.

! Please note that the rebuilder does NOT rebuild samples!

Not rebuild? Okay lets copy all samples from our current folder into that 0.139 sample folder. From

....to.

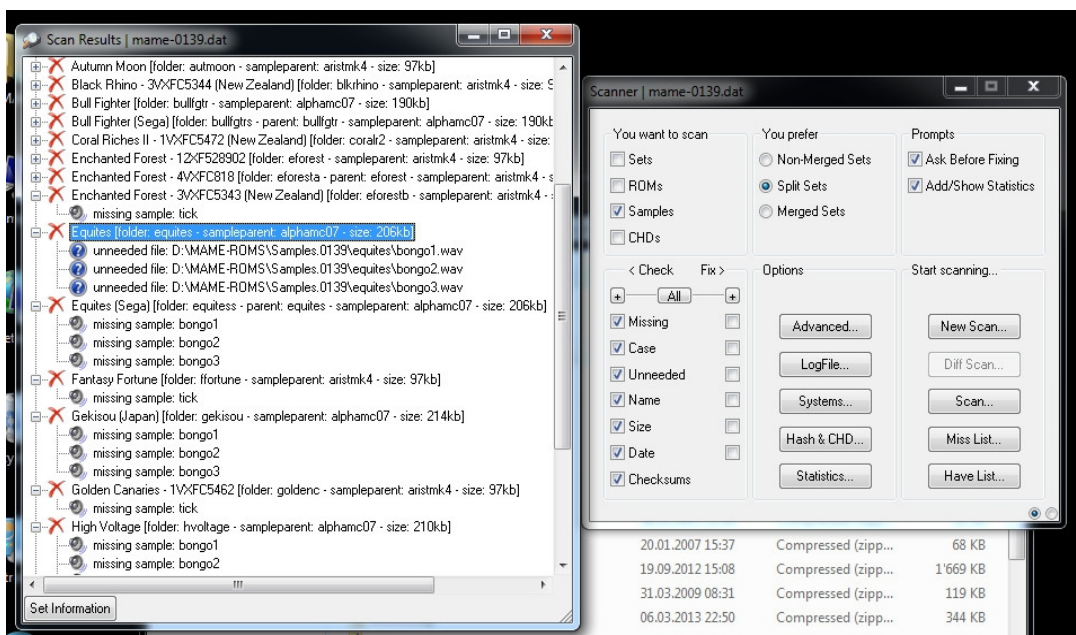

Do another scan and we have still missing and unneeded...

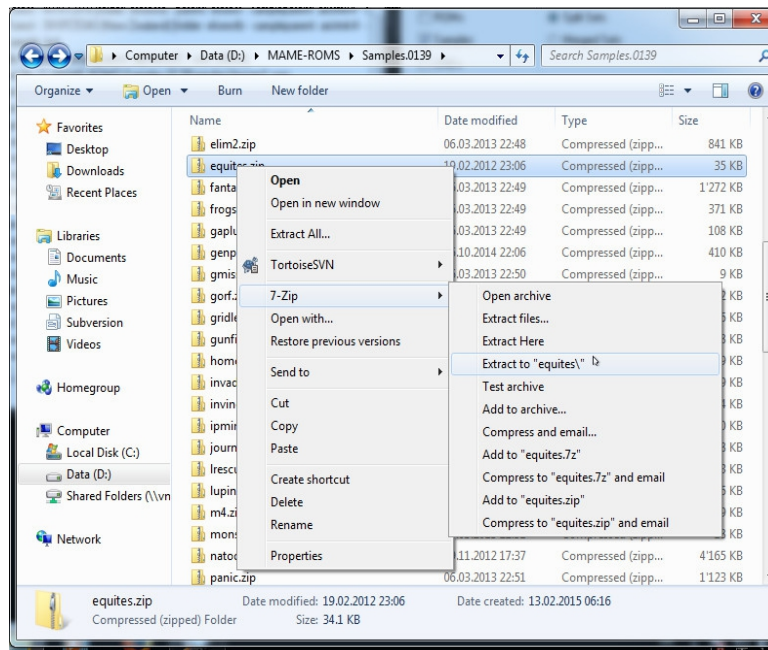

We look deeper to our missing and we see that “equites” has some samples that should be in “alphamc07”.

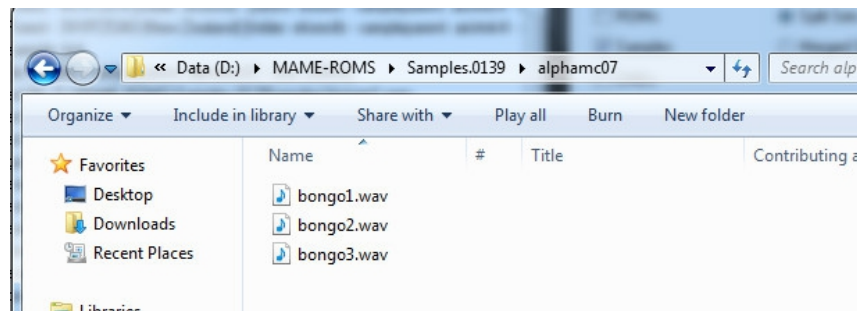

We extract this “equites.zip” into a folder.

And rename this folder to “alphamc07”

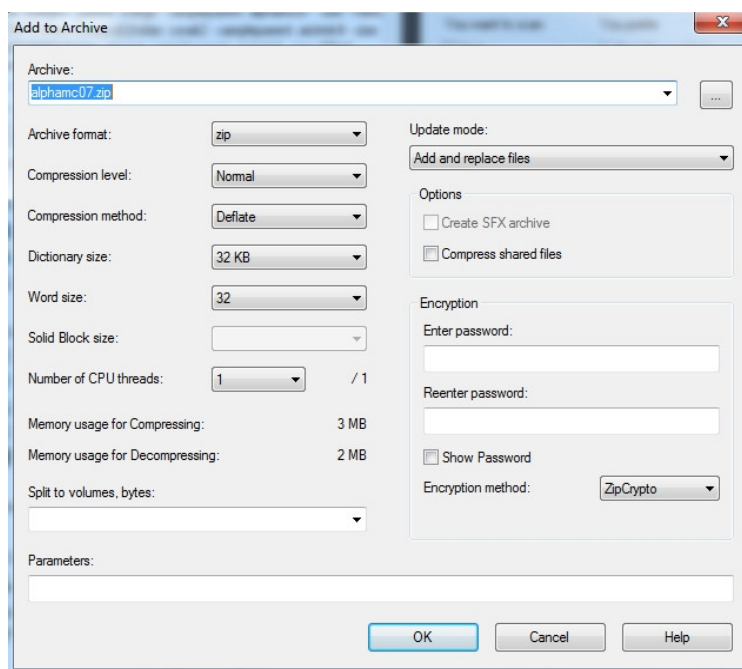

We zip this folder now ...

...into a file called “alphamc07.zip”

After we have created this zip-file delete the folder and do another scan.

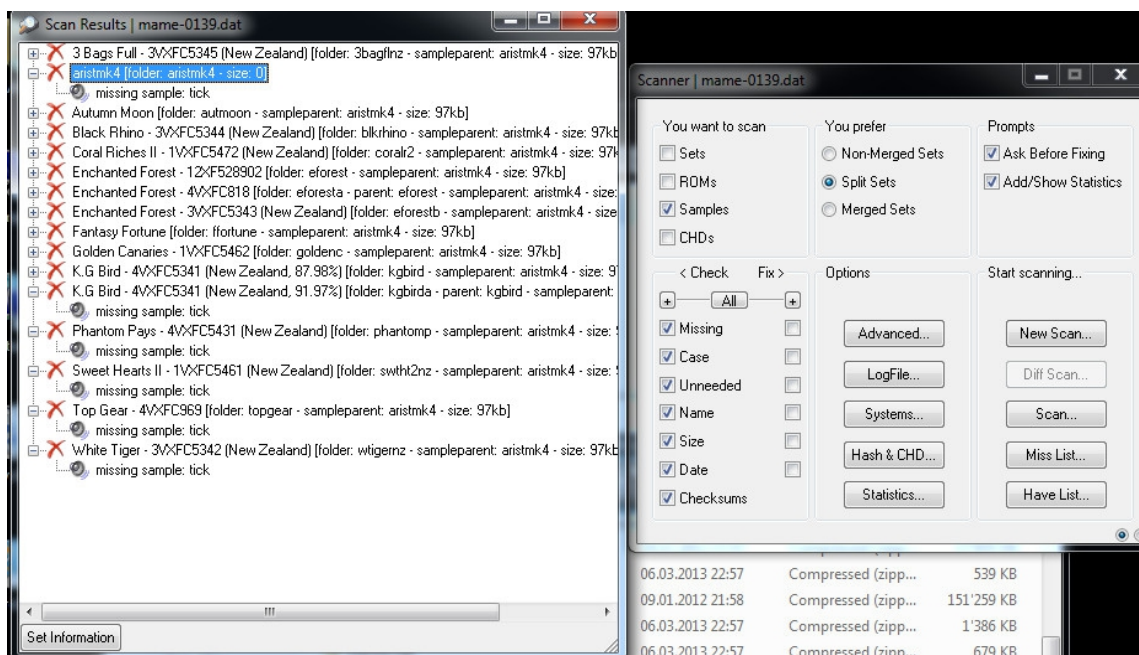

Search on the Internet for the missing sample, one of the source is AntopISA.

One of the sample we found there is “wotwc.zip” → place it into the 0.139 sample folder.

Do another scan. We see that this “tick.wav” is missing a lot.

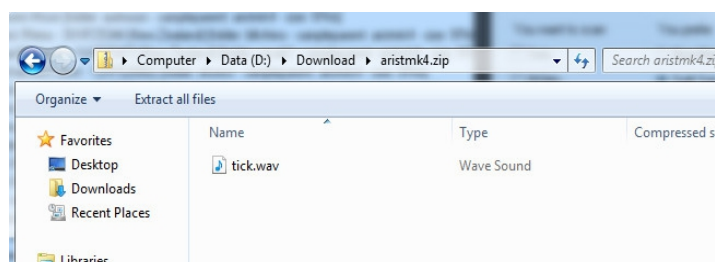

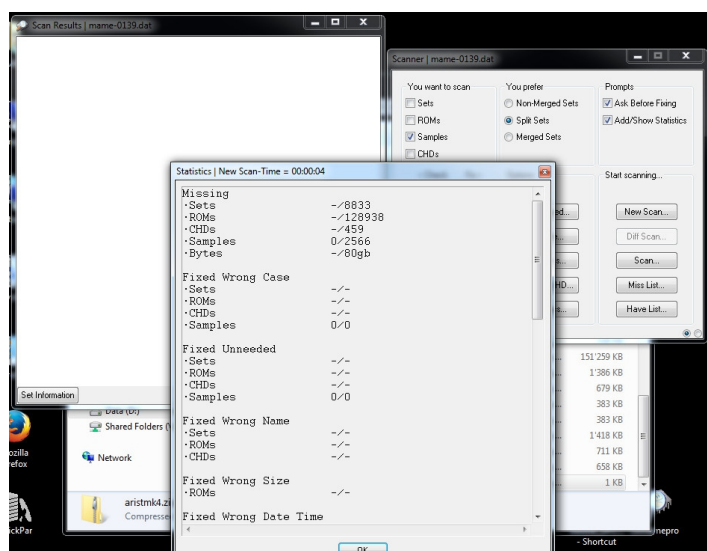

Go to Twisty's Sample page and download this “aristmk4.zip”

Game Name	File Name	Size
Alpha Denshi Games	alphamc07.zip	34KB
Aristocrat Games	aristmk4.zip	1KB
Armor Attack	armora.zip	988KB
Astro Blaster	astrob.zip	1,990KB
Astro Fighter	astrof.zip	755KB
Barrier	barrier.zip	128KB
Battles	battles.zip	368KB
Blockade / Blasto / Commotion	blockade.zip	12KB
Buck Rogers	buckrog.zip	914KB

Yeah this sample have this “tick.wav” inside.

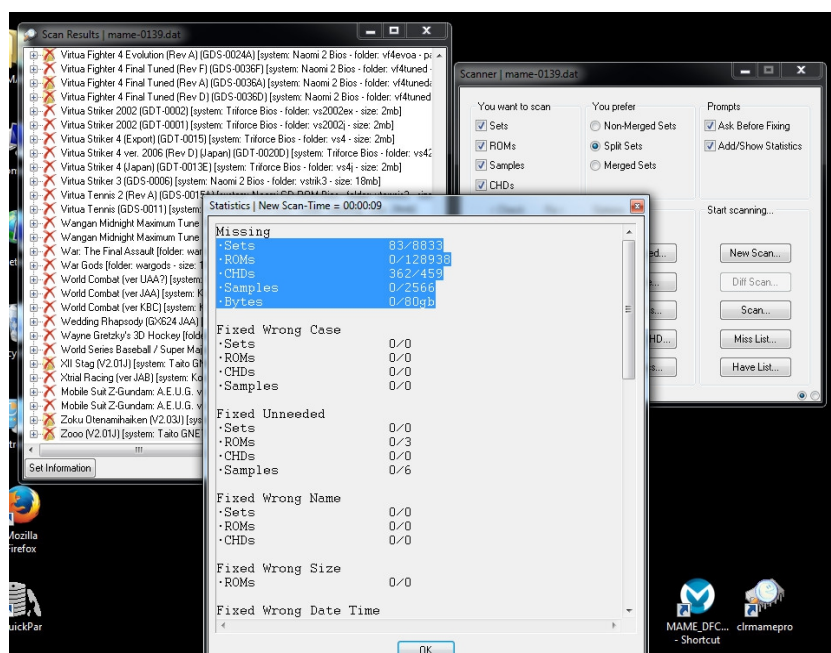

Move it to the 0.139 sample folder and do another scan.

We have now ROMs and Samples complete.

We miss only CHDs and those are very difficult to go back in version. To have a complete 0.139 CHD-set you may need some removed CHDs. They are also available in a set called “rollback CHD-set” on the Internet. And a lot of CHDs have to be downgraded their version to a lower number. We are now at Version 5 for the CHDs. There is no official way to go back in the version, I mean “chdman.exe” does not provide that.

As CHD based games needs power on the running machine it does makes no sense for those few games to have them.

That's the reason I give you no answer to a “how-to CHD rollback”, sorry ;-)

Enjoy playing games with your 0.139 MAME emulator (you know how to handle it and find his ROMS/Samples)

Scanning a set that has nothing to do with ROMs

If there is a DAT-file available we can use CLRMAMEPRO for checking other items than ROMs or CHDs (created for example with Dir2Dat). We have for example the titles-snapshots in our MAME folder.

Maybe you have noticed at the “Progetto-Snaps” homepage provide also DAT-files for all his snapshots. Let's open a web-browser and go to the page. Under “Titles” you will find the DAT-file, download it.

Extract the downloaded zip-file.

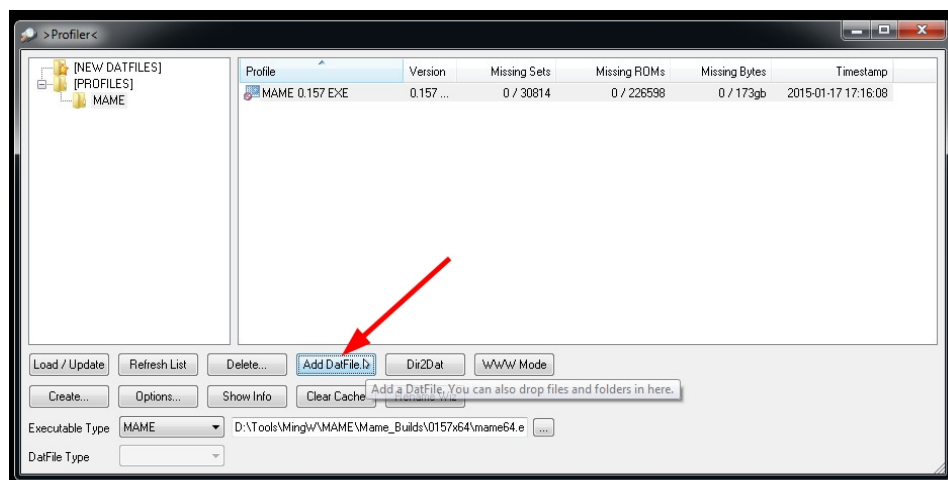

Start CLRMAMEPRO

Click “Add DatFile” in the profiler

Navigate to your download folder where the DAT-file is located

The question where to store the DAT file appears.

We create a new folder for that DAT called “MAME_Addon”

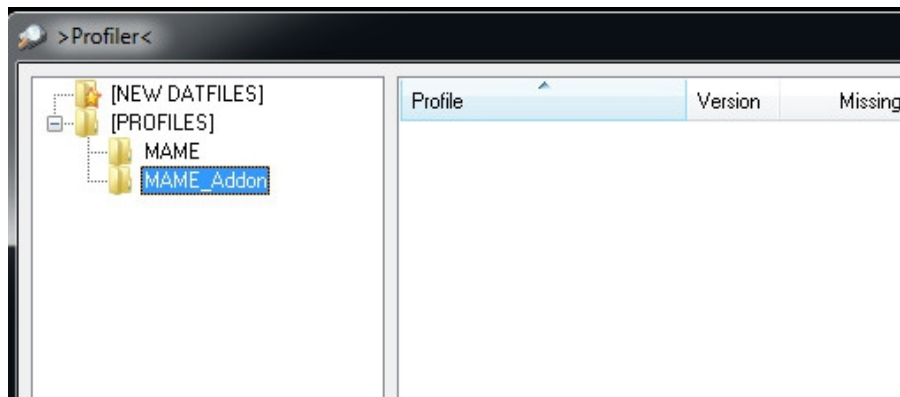

And choose that folder → OK

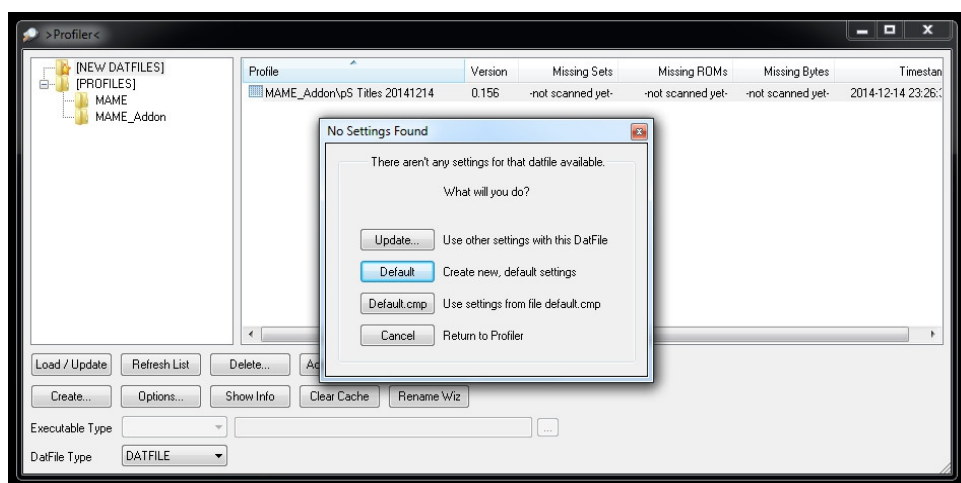

Where is the added DAT-file?

Yeah right, all not used DAT-files are under “New DATfiles”

Load that DAT and choose “Default” settings

Open “Settings”

Add the path to your titles in the ROM-Path ;-)

We start now the scanner

Start a “New scan” and at the end it will display the summary.

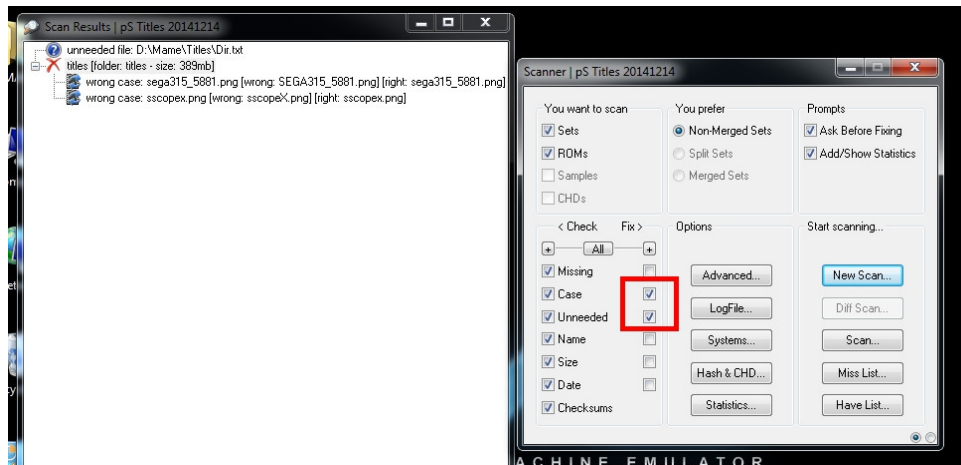

Okay nothing is missing but it is not perfect. It complains that it contains a unneeded txt-file and two snapshots has a wrong case.

We have already learned how to correct ROMs with the scanner. We will do it too with the snapshots. Enable fix for “Unneeded” and “Case” and start again a scan.

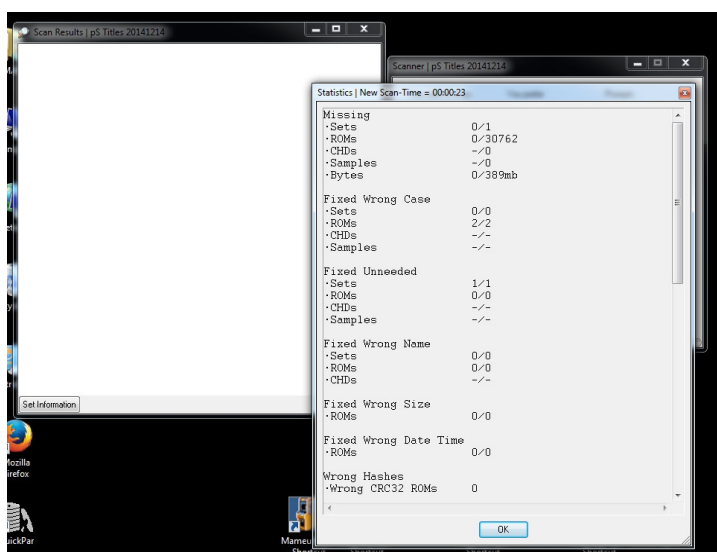

Click “Yes too all” ... (yeah right it is only 1 file that needs to be removed)

Next question is about the Case. CLRMAMEPRO displays you details what it want to rename. If you want to have this question for each Case click “Yes” otherwise if you want all Case problems solved without asking click “Yes to All”. When you are unsure you can click “Yes” and see on each problem what CLRMAMEPRO will do. I think at the beginning it is good to do it step by step and see that CLRMAMEPRO does a fabulous job :-)

When it has finished the scan should look like that.

We are now fine our titles-snapshots are verified with the DAT-file.

! Additional : I will give you some more information about scanning add-on files.

We are looking now into that DAT-File.

As we can see there is only one hash (CRC) available for the snapshot.

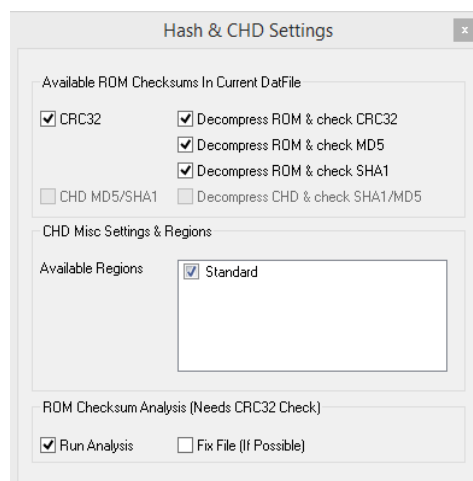

When we look into the “Hash & CHD” Settings we see that we can not enable for example MD5 or SHA1. That's the reason why, it is not included in the DAT-file.

I'm opening another DAT-file just for showing you the difference.

```

```

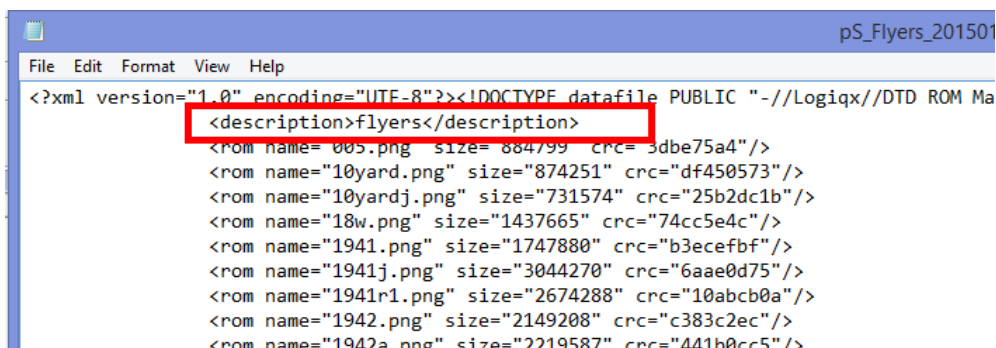

As we can see those snapshots has a CRC, MD5 and SHA1 hash. When we open the “Hash & CHD Settings” we can enable those for our scan.

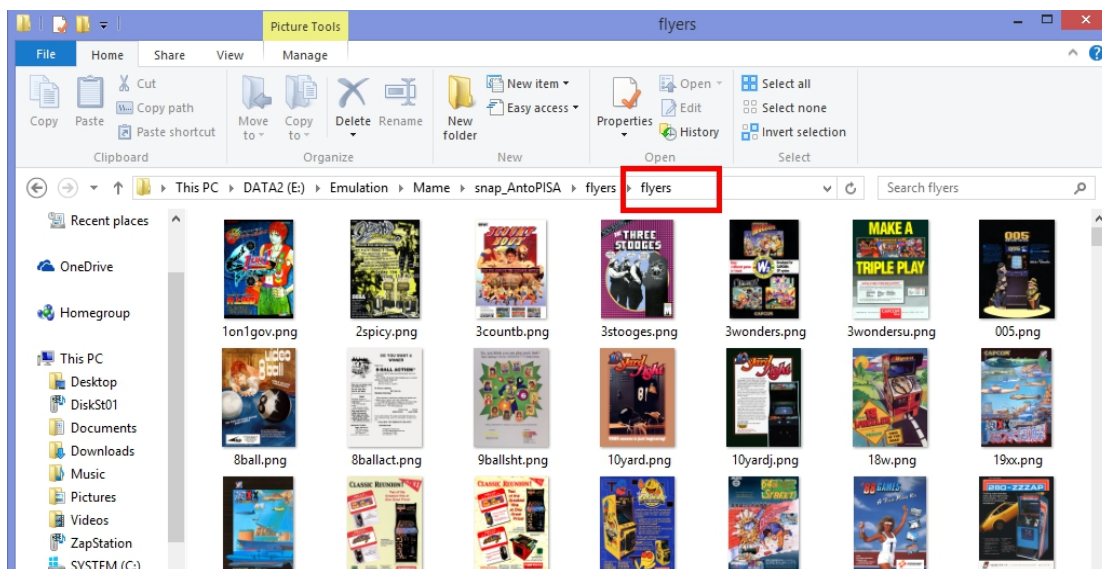

And another information. If we have add-on that are really big like the flyers (over 5 GB) it is maybe not the best solution to pack those into a Zip-file ;-)

Let's open this DAT-file and look for some details.

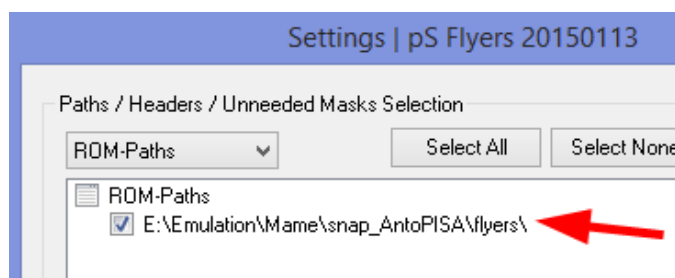

```
<?xml version="1.0" encoding="UTF-8"?><!DOCTYPE datafile PUBLIC "-//Logiqx//DTD ROM Ma
<description>flyers</description>
<rom name="005.png" size="884799" crc="3dbe75a4"/>

<rom name="10yardj.png" size="731574" crc="25b2dc1b"/>
<rom name="18w.png" size="1437665" crc="74cc5e4c"/>
<rom name="1941.png" size="1747880" crc="b3ecefbf"/>
<rom name="1941j.png" size="3044270" crc="6aae0d75"/>
<rom name="1941r1.png" size="2674288" crc="10abcb0a"/>
<rom name="1942.png" size="2149208" crc="c383c2ec"/>
<rom name="1942a.png" size="2219587" crc="441b0cc5"/>
```

CLRMAMEPRO will look for a flyers.zip or a flyers folder to where you have set your ROM-Path. If you want to have the flyers unzipped be sure that they are in a folder names “flyers”. For example:

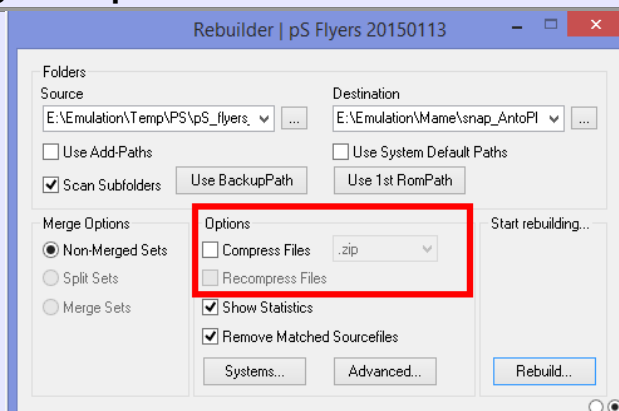

Set your ROM-Path in CLRMAMEPRO to the folder one up.

It will scan this folder for the flyers and found them in the subfolder “flyers”.

! If you rebuild missing snapshots be sure that you disable this setting and point it to the folder where the snapshots are. Otherwise it will generate a “flyers.zip”

Create an add-on snapshot folder with the rebuild function

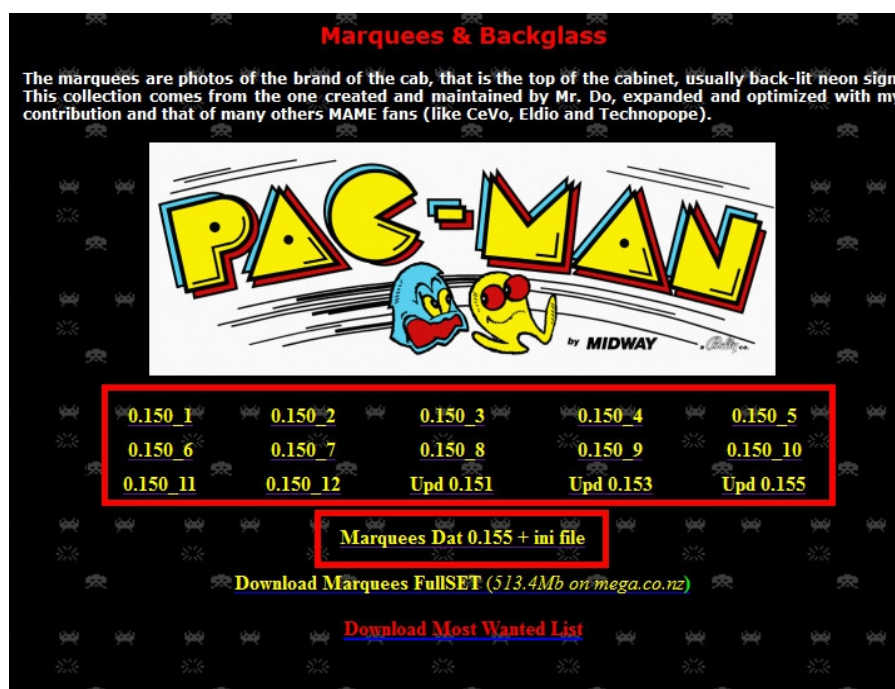

We have seen in the add-on section that downloading a complete snapshot packages is the easiest way to have the snapshots available in your MAMEui. Not for every category on the Progetto-Snaps homepage are complete packages available. We show you now how you can use the rebuilder to create a complete add-on set. In our example we take the marquees snapshots.

Open a web-browser and navigate to the category Marquees on the Progetto-Snaps site.

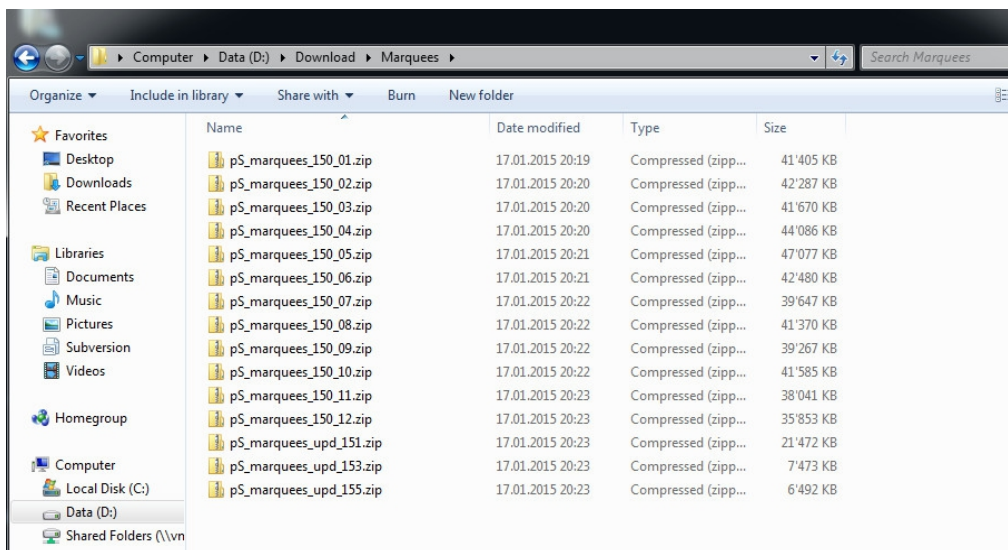

Download all parts that are available and the DAT-file.

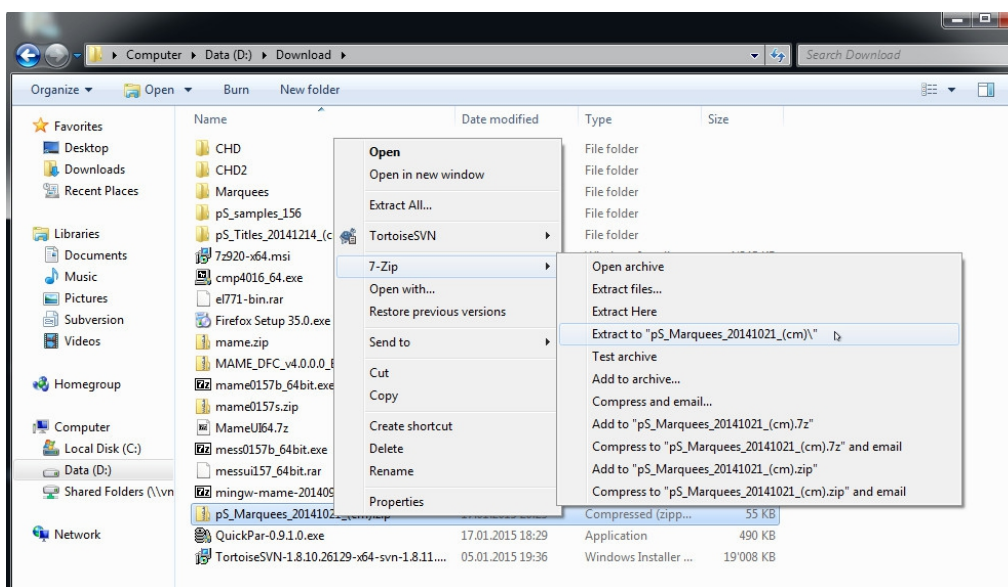

Create a “Marquees” folder in your download. Move all downloaded files to this folder.

MAME/MESS The Guide

The DAT-file you must not move to this folder but extract it to a separate folder.

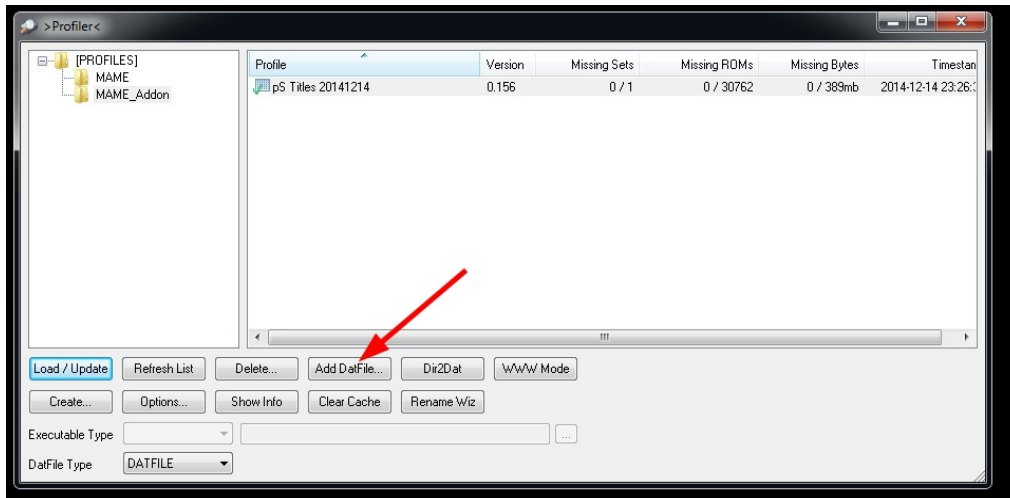

Start CLRMAMEPRO

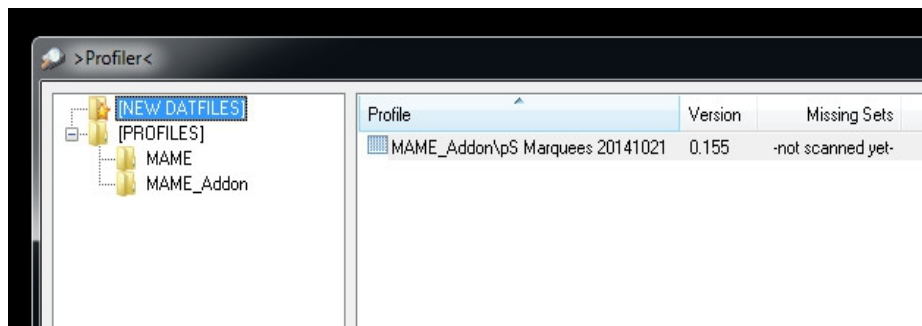

Add the extracted marquees DAT-file

And put it to the “MAME_Addon” folder

Load the added file into the profiler

Load it with “default” settings

First task? Yes we must go to the “Settings”

.. and set the ROM-Path to our Marquees folder in MAME

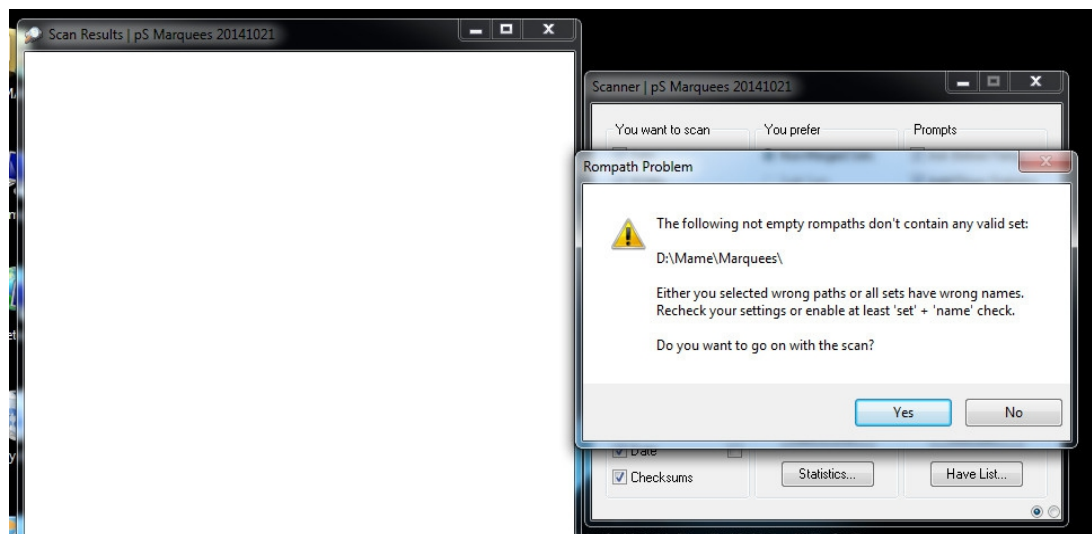

Start the scanner

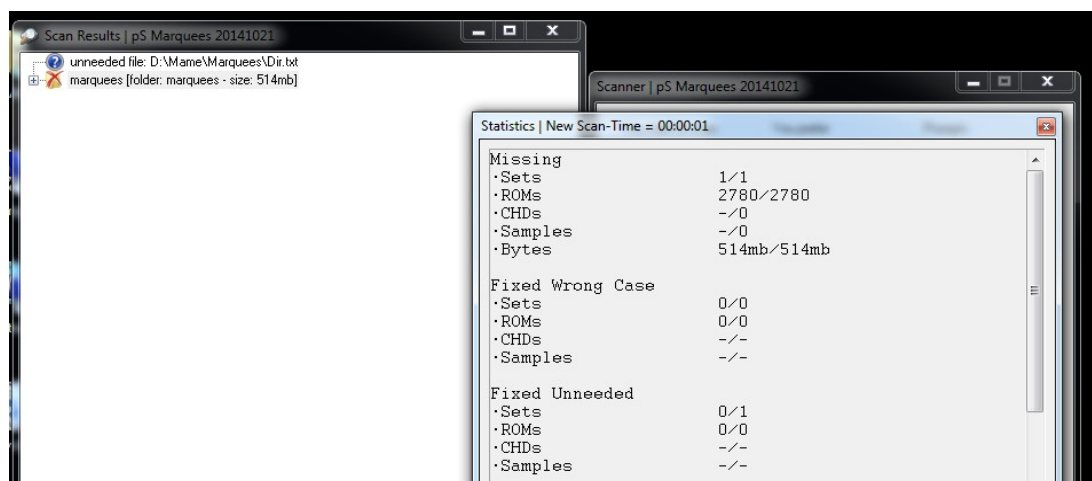

It will complain that nothing is inside that folder, click “Yes”

! CLRMAMEPRO will do a “quick scan” before the Scanner is available. That's the reason why we have received this message.

- Sometime it is good to have this information before you start the scan process. When you have for example pointed your ROM-folder to the wrong directory.

After the scan has finished we know now that we miss all marquees, fine ;-)

Close the scanner and start the rebuilder.

Point the "Source" folder to your marquees folder in downloads.

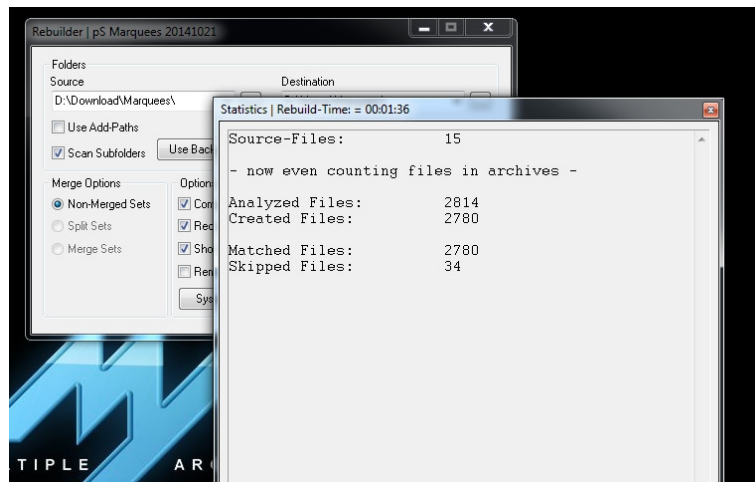

The rebuilding process has started

The rebuilding has finished and “Matched Files: 2780”, that's sound great.

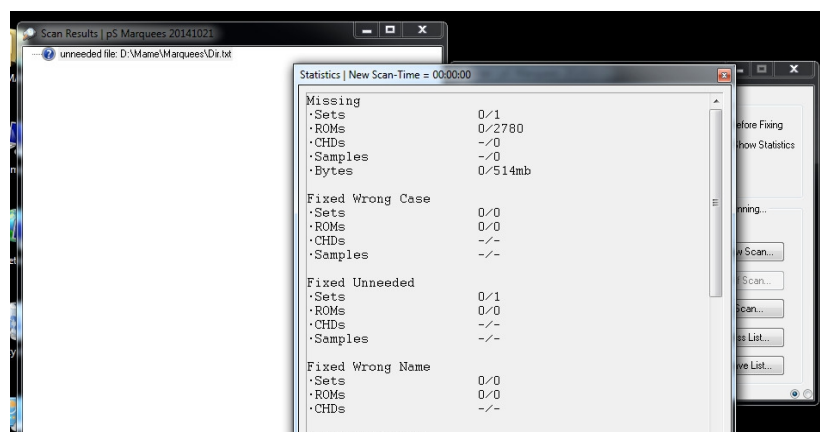

We have now a new created “marquees.zip” in this folder.

Start the scanner

We have now, oh yes, zero missing and an “unneeded”

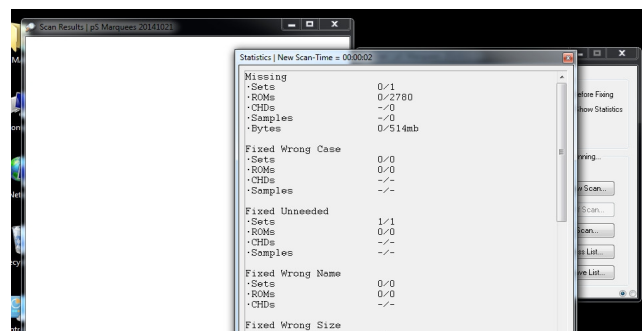

MAME/MESS The Guide

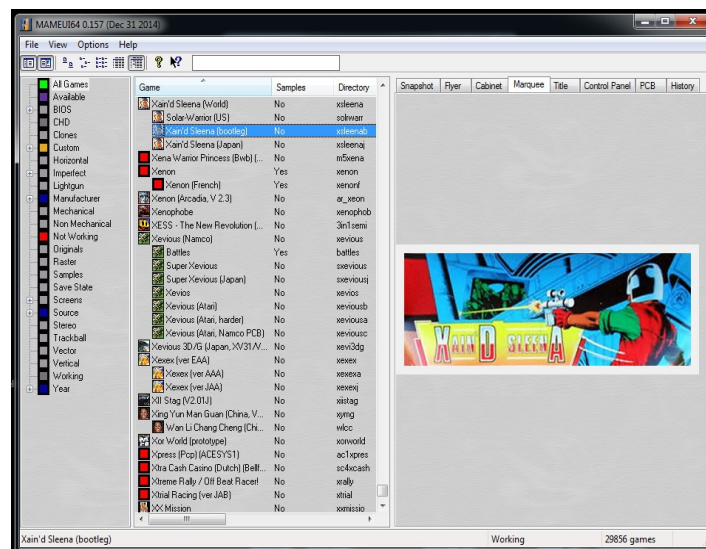

We can scan again with this “fix” enabled

And now we have a perfect complete marquees snapshot set.

With MAMEui we see the marquees now.

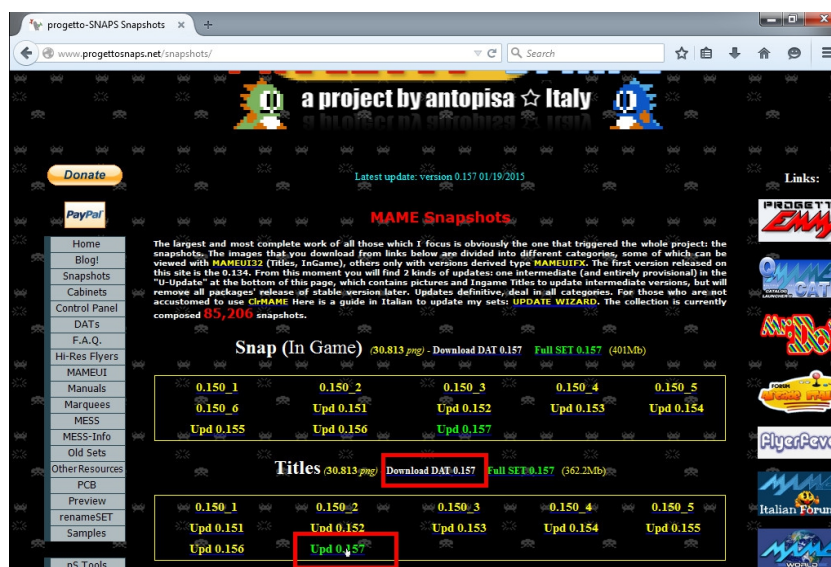

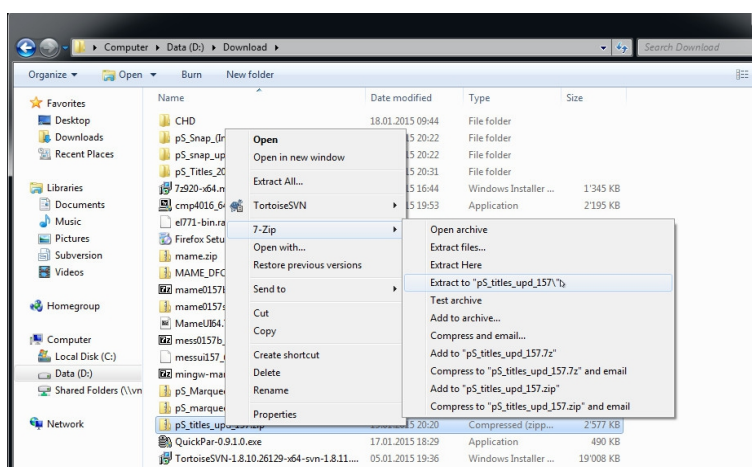

Updating an add-on folder with CLRMAME

As you may have seen we have installed MAME build version 0.157 and the add-on examples was for version 0.156. In the meantime AntopISA has releases a 0.157 update to all his snapshots. We try now to update our titles-snapshots to version 0.157.

Open a web-browser and navigate to Progetto-Snaps and choose “Snapshots”. Download the update and the DAT-file for 0.157.

Extract both files to a subfolder within the download-folder

Start CLRMAMEPRO

Add the downloaded DAT-file in profiler

Add the “ps Titles 20150118” DAT-files to the “MAME_Addon” profile folder and load it into the profiler

What's that? Huh? It has checked that there is an old titles DAT-file already in CLRNAMEPRO. As this DAT-file should replace the old one we choose “Yes”

! When you choose “update” be sure that it displays the right old DAT-file. Otherwise it replace the wrong DAT-file.

We choose “Settings” as our first step before scanning

Adds the titles ROM-Pathshmm it is already the right path there.... Can you remember we have chosen “update” and it has taken the settings from the old DAT-File.

Okay we are heading now to the scanner

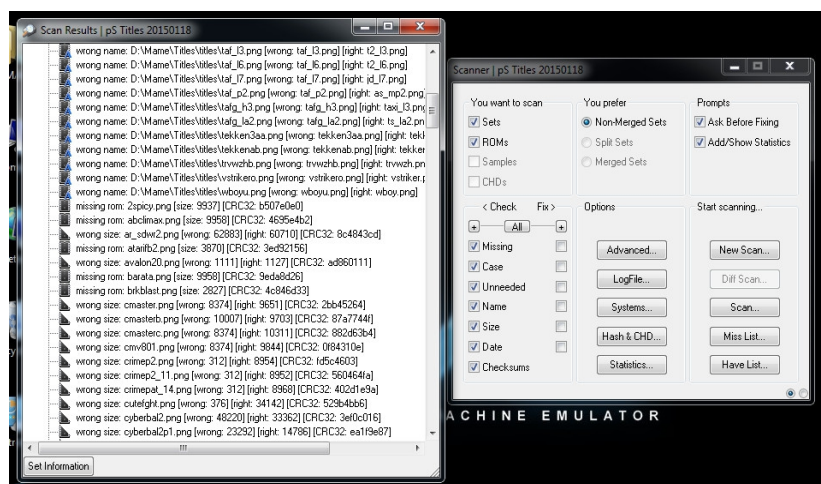

And choose “Diff Scan”, but it is not available, why? The reason is very simple. This DAT-File has only 1 Set called “titles” and it is “new” or “changed” → In that case we can only do a “New scan”

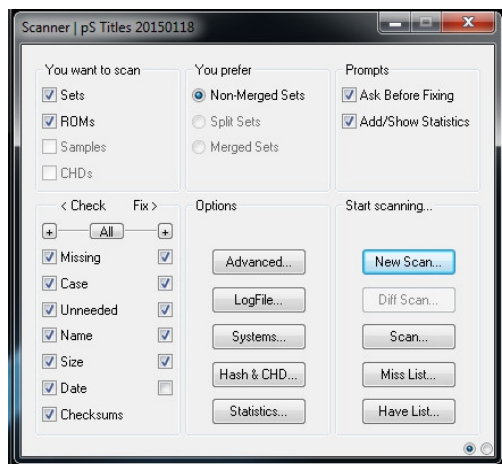

! We will see in a next chapter “update DAT...” more information for this update function.

After the scan has finished we see in the “Scan Results” window that there are missing, wrong named or wrong size messages.

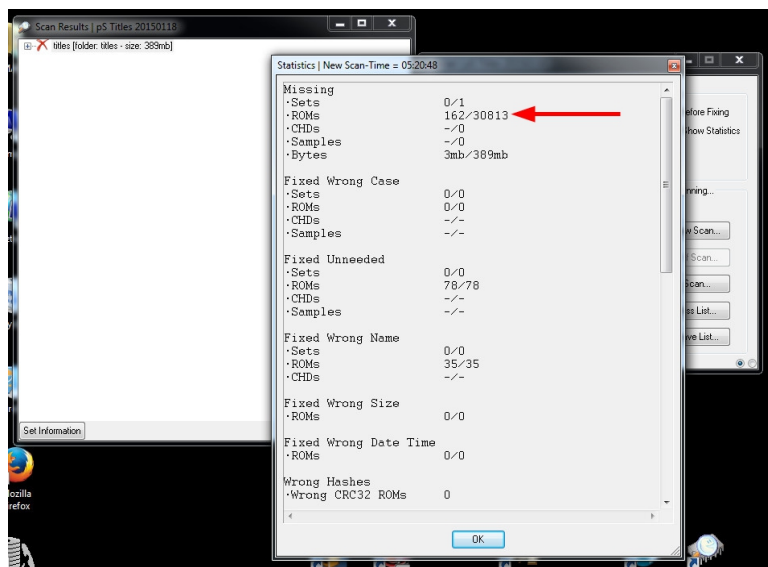

Let's do another scan with the fix options enabled.

We reply to each question “Yes to all” → let's fix CLRMAMEPRO everything that is possible.

And we have now a “clean” set but with missing snapshots.

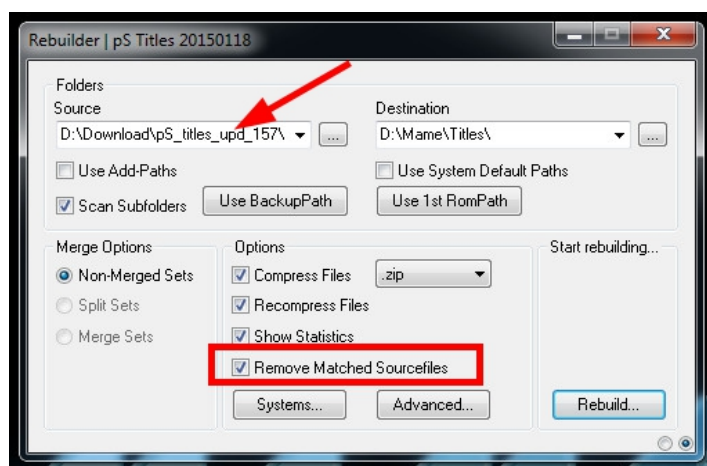

Use the rebuilder now

Point the source to the folder in the downloads where you have your extracted titles-snapshots. Enable “Remove Matched Sourcefiles”.

After the rebuild it displays the statistics

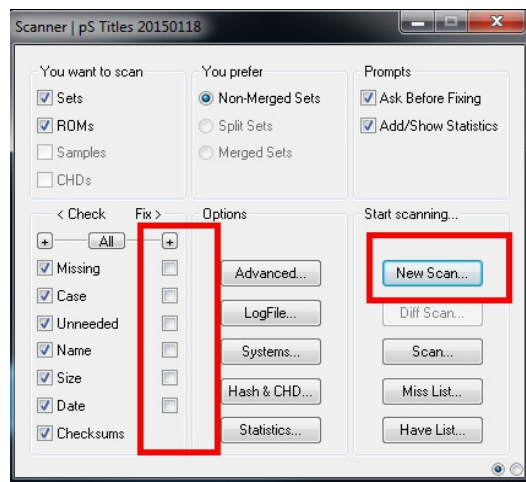

Use the scanner again

We disable all enabled fix options and start a “new scan”

and and and? Yes we have now again a complete set for 0.157

Using a DAT-file as an update for an existing DAT-file

We look again in the “update” procedure with existing DAT-files.

Start CLRMAMEPRO

We add now a new DAT file, click “Add DatFile”

We choose one of the DAT-File we have created with DFC.

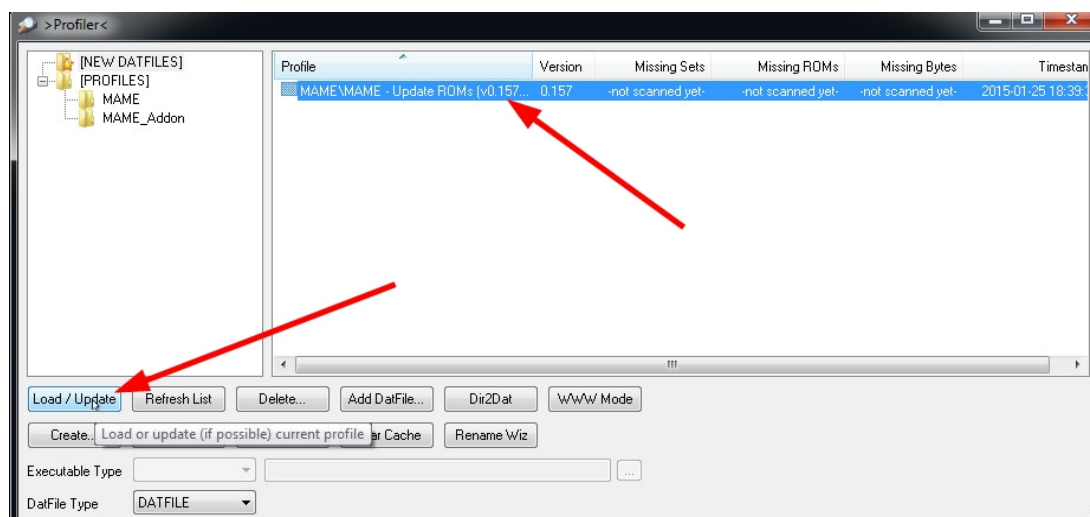

Place it in “MAME”

Load that added DAT-file

Choose “default” settings

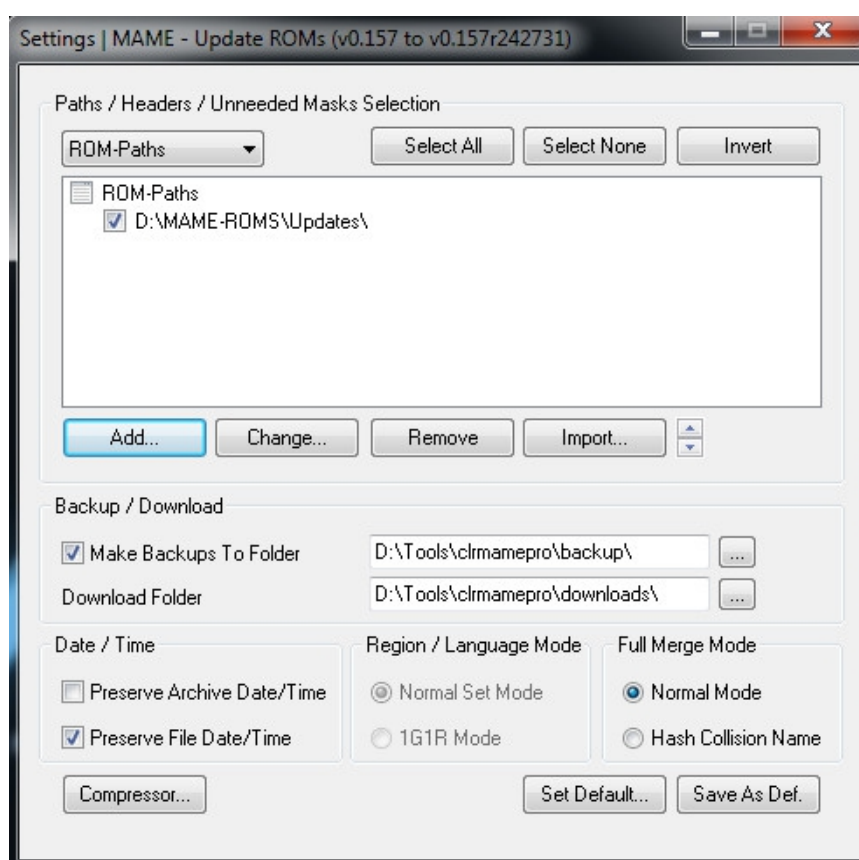

Go to “Settings”

Set the ROM-folder....

And start “Scanner”

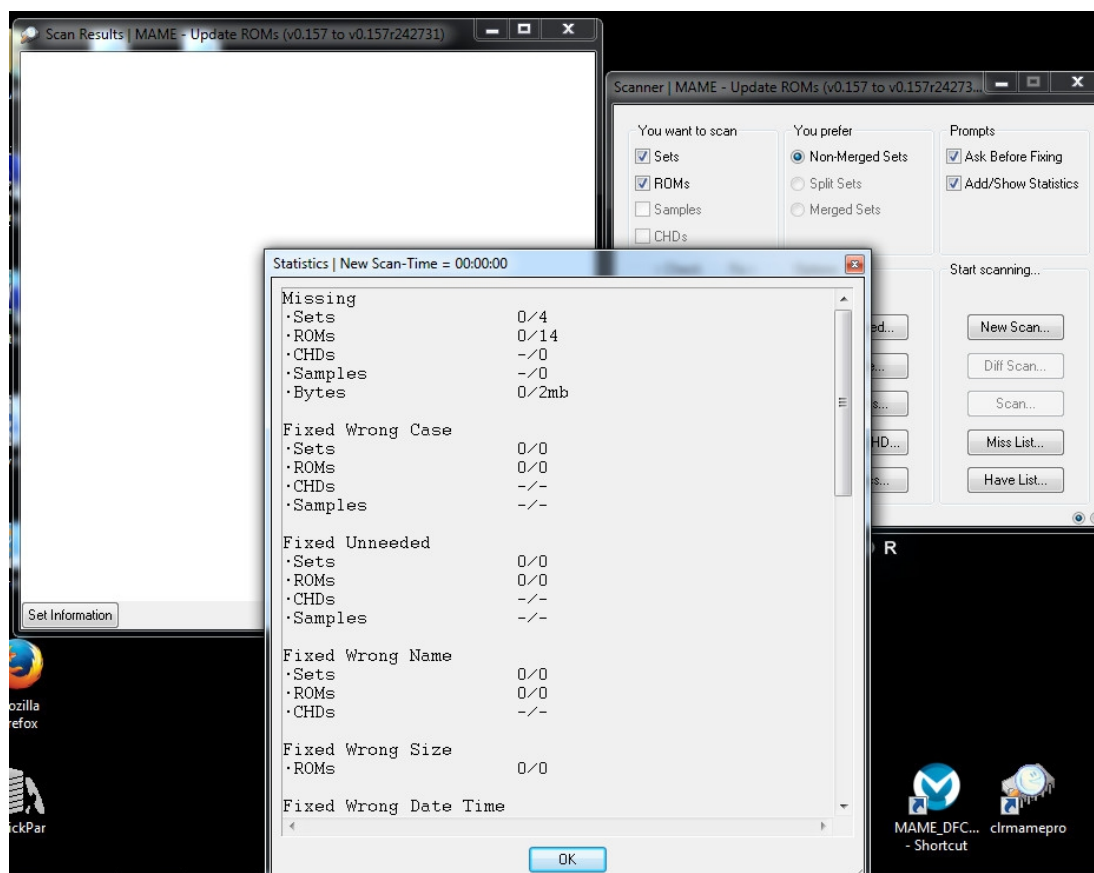

Start a “New Scan”

Our update ROM-Folder is complete.

In the meantime there is a new MAME build available (update between V0.157 and 0.158) and we do have created a new update DAT-File.

Go to Profiler (that brings you back).

And we want to add this new update DAT-file

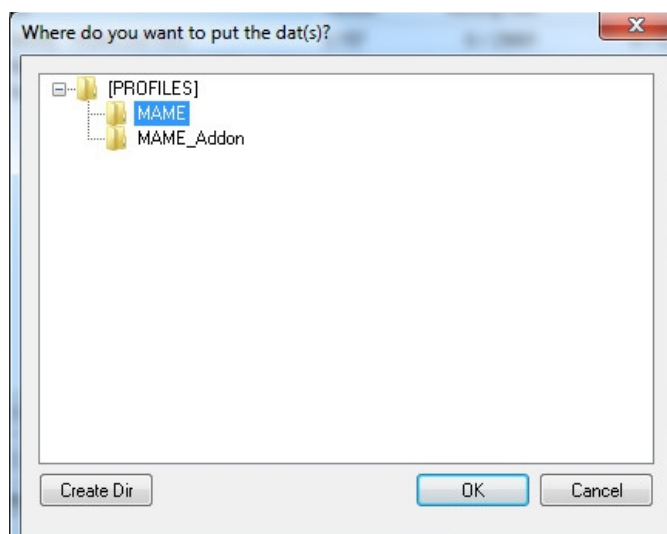

Choose the new DAT-File ..

And place it to our “MAME” profile folder.

We load now this new added DAT-file.

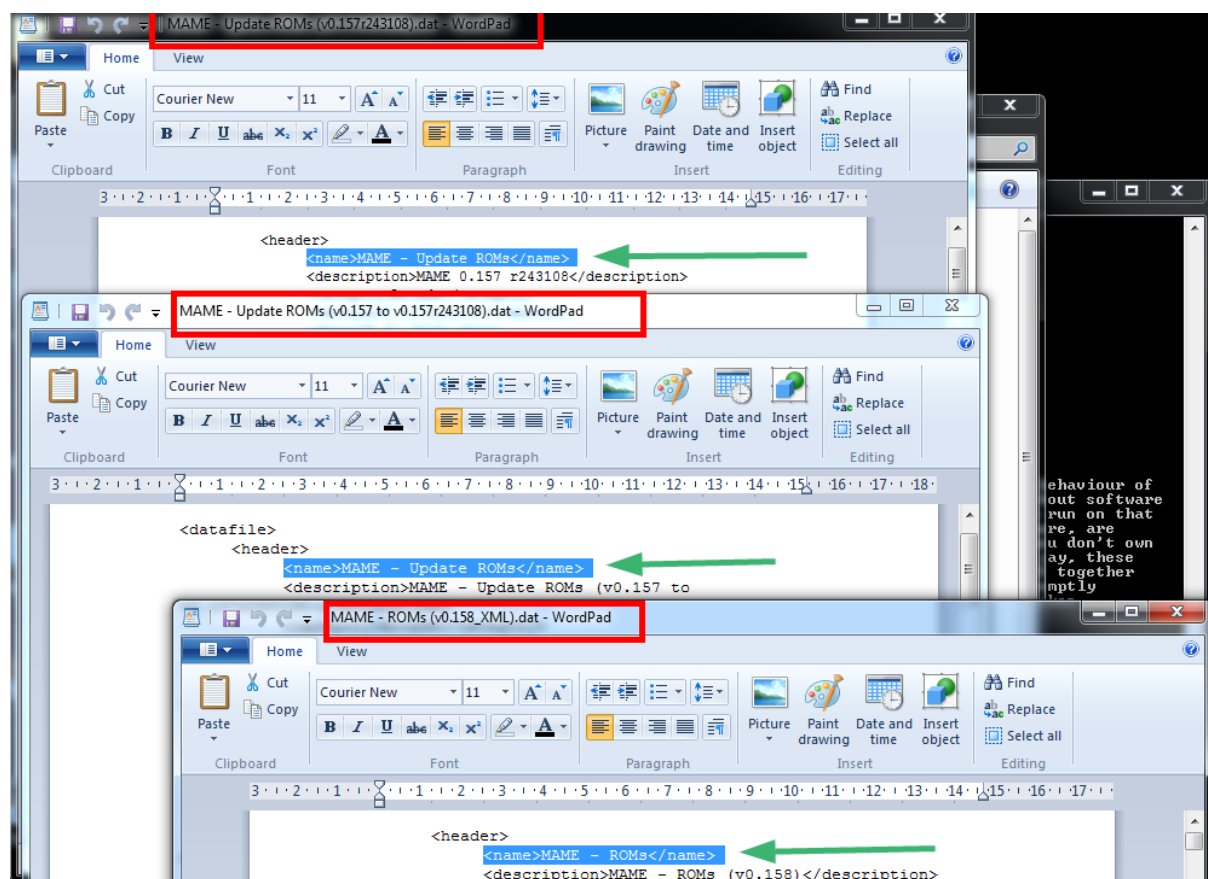

As inside the DAT-file is the same description CLRMAMEPRO does scan that and does offer an “update procedure”.

Why does CLRMAMEPRO knows that we have already a DAT-file that can be updated? The answer is simple, let's look inside three DAT-files.

In the “header” section we have this tag “name”. For this update ROMs-DAT-file it is called “MAME Update ROMs” in both files. When we look into the full ROMs-DAT-file it is called “MAME - ROMs”. That's why CLRMAMEPRO think that this new added DAT-file should replace the other one. Be warned that when you are creating a lot of DAT-files for example for MAME-FX or MAME-ASH you don't want to remove/update the DAT-File.

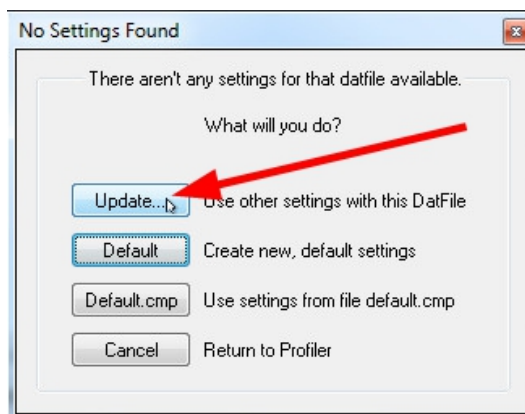

We see now that the new “Description” is displayed and the DAT-file that CLRMAMEPRO has detected as an update. Also the “Description” is displayed. You now have to choose “yes this is true” or “no this is not true or the wrong DAT-file is displayed for an update”

! When you do an update all settings/cache from the previous DAT are copied to the new one. The old DAT file will be deleted.

In our case it is true, we could click “yes” but I will show you what to do if a wrong DAT-file is displayed for an update. Click “NO”.

Now we see the normal “no settings found” window. Now choose “update”

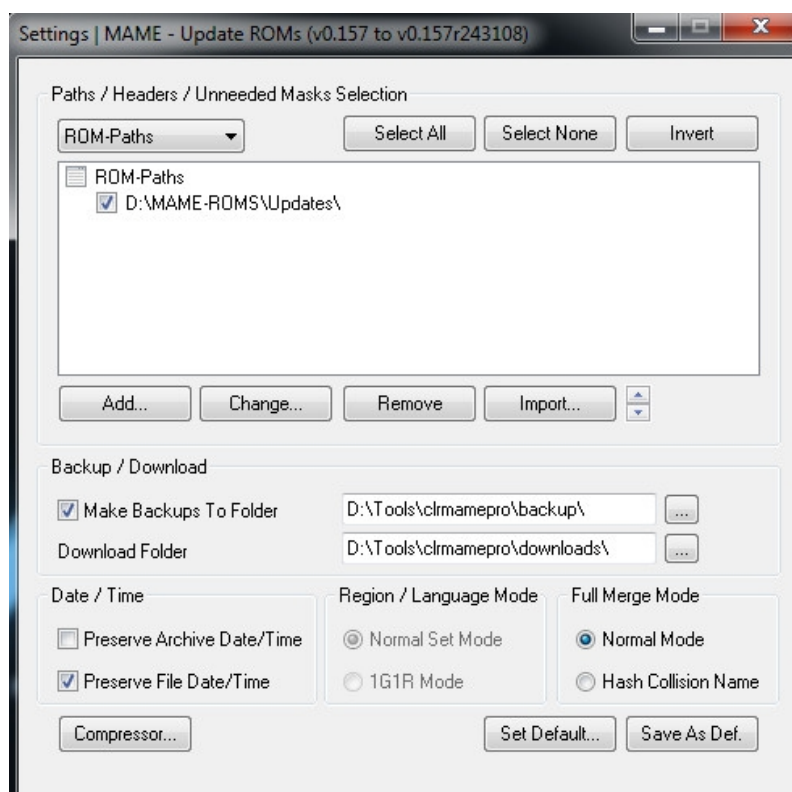

A new window is opening. There you see all available DAT. Choose the right one and click “update”.

We have now replaced the old one with the new one. When you are going now to the “Settings” you see that the ROM-path is already set (yes it was copied from the old one).

In the “Scanner” you have now also the choice to do a “Diff scan”. This function does detect what has changed from the old-DAT to the new one.

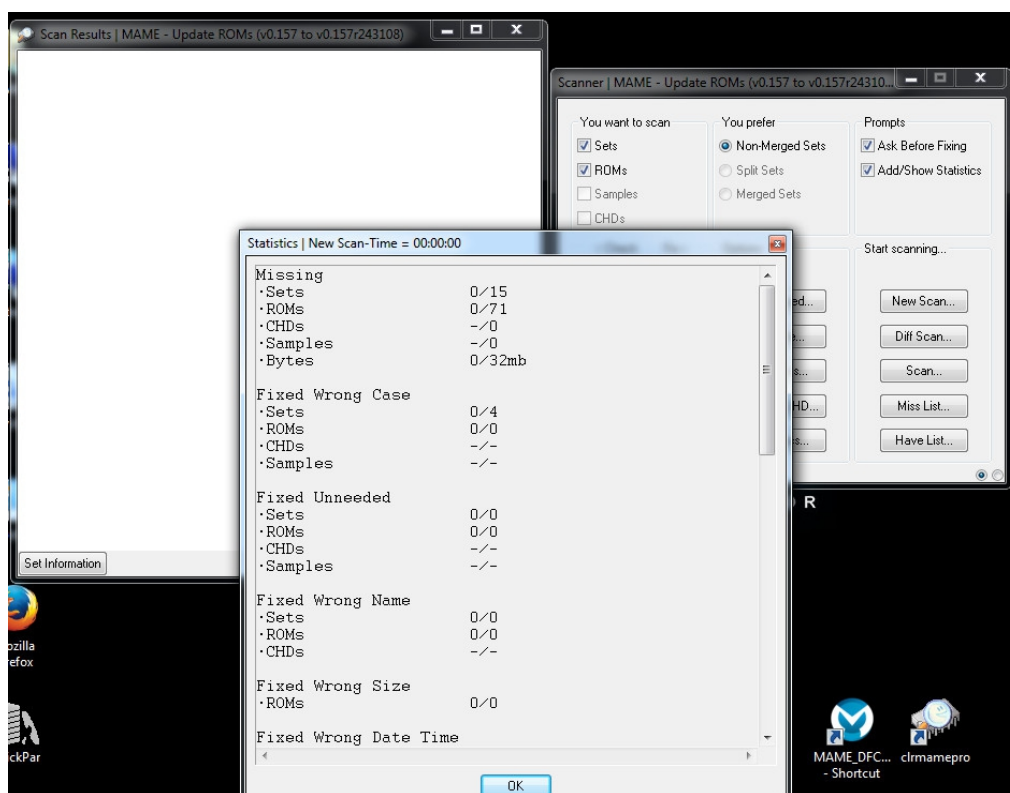

! Attention: When you have missing sets in the previous DAT-file and you are doing now this “Diff Scan” with the new update DAT-file

- they are NOT being displayed. Do in that case a “New Scan” to be sure that you have everything reported.

We update our update ROM-folder and do a “New Scan”.

Note that in the profile is the old DAT-file not more available (yes it has been replaced by the newer DAT ;-))

Chapter 7: Compiling MAME/MESS

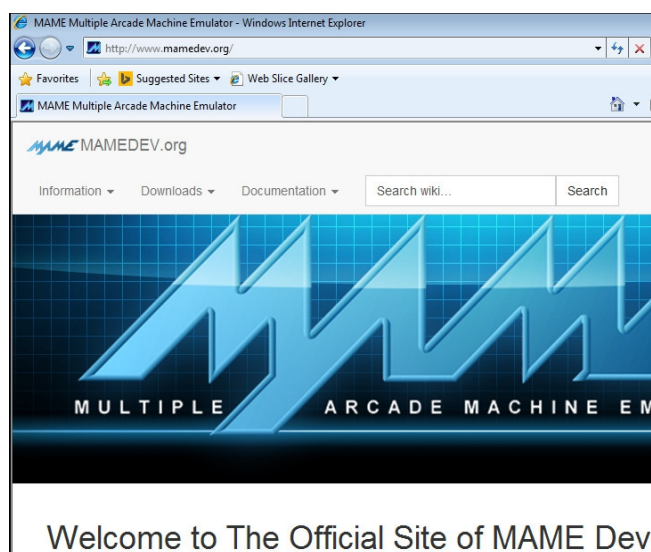

A lot of people are now happy. Playing their games and never updating their systems. MAME/MESS is an ongoing project, new systems are being added, added are updated. There are two way to have the latest emulator installed. Waiting for a new version to install or compile their own version with the source code. Compiling MAME/MESS have again two ways to do it: download the source-code, compile it or using the online repository for downloading the latest source-code and compile it afterwards.

At the moment every month is a new official MAME version published. The need for doing an own compile is only when you need a special version or when you are hunting for new ROMz yourself ;-)

Compiling with full source code

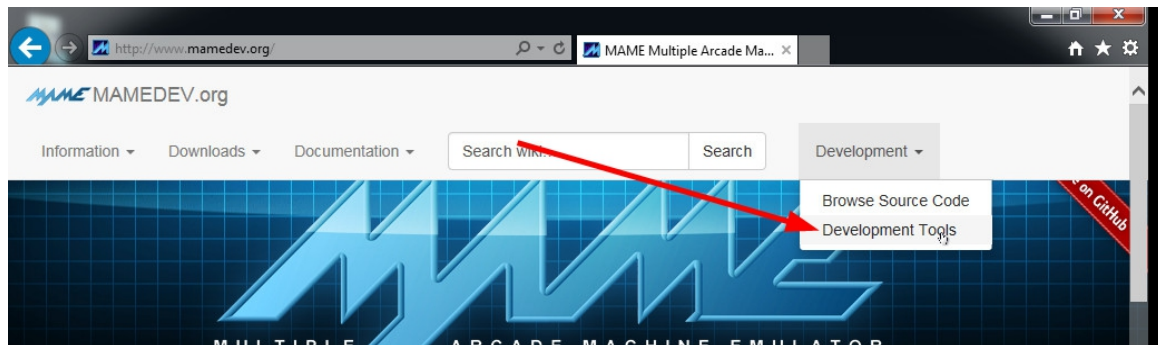

Installing the needed Compiling tools

Open a web-browser and navigate to the MAMEdev.org site.

Under Development choose “Development Tools”

There is an “install.exe” for downloading.

Tools for building MAME on V

1. Download [install.exe](#) and complete installation. It will take some time to pull up-to-date code
2. Start [buildtools.bat](#) (plain cmd) or [cmdex.exe](#) (fancy console) from installed folder (by default it is C:
3. From time to time run **update** in order to update tools
4. Download MAME source

git clone https://github.com/mamedev/mame.git
Console emulator is based on Cmdex, with some small changes in scripts.

Save it to our Download-folder. Create a new folder “MAMECompiling” under “D:\Tools\”

Start the “install.exe” and choose the new created folder.

This install tool will download now from the MAME repository (Where the MAME program source is) all needed compiling files.

After it has finished there are all required files in that folder.

Start the “buildtools.bat” and

.. it does do set some settings once in your environment.

We change to the “bin” folder. There is an “update.bat” that you can start. It does check if there are newer tools available and does download it. I don't know how often this will happens. Execute that “update.bat” from time-to-time”

```
C:\Windows\system32\cmd.exe
D:\Tools\MAMECompiling\src>cd ..
D:\Tools\MAMECompiling>cd bin
D:\Tools\MAMECompiling\bin>update.bat
```

Okay not a surprise we are “up-to-date”

```
C:\Windows\system32\cmd.exe
D:\Tools\MAMECompiling\src>cd ..
D:\Tools\MAMECompiling>cd bin
D:\Tools\MAMECompiling\bin>update.bat
Updating MAME tools
=====
Already up-to-date.
D:\Tools\MAMECompiling>
```

! Do NOT use a command-line window that you have started somewhere else than starting it with this “buildtools.bat”. Otherwise the update and compiling function does NOT work!

We have now installed all required compiling tools and what do we need next? Ah yes we need the full source-code for MAME. This new compiling tools have everything available, also downloading the source-code without the need of a web-browser.

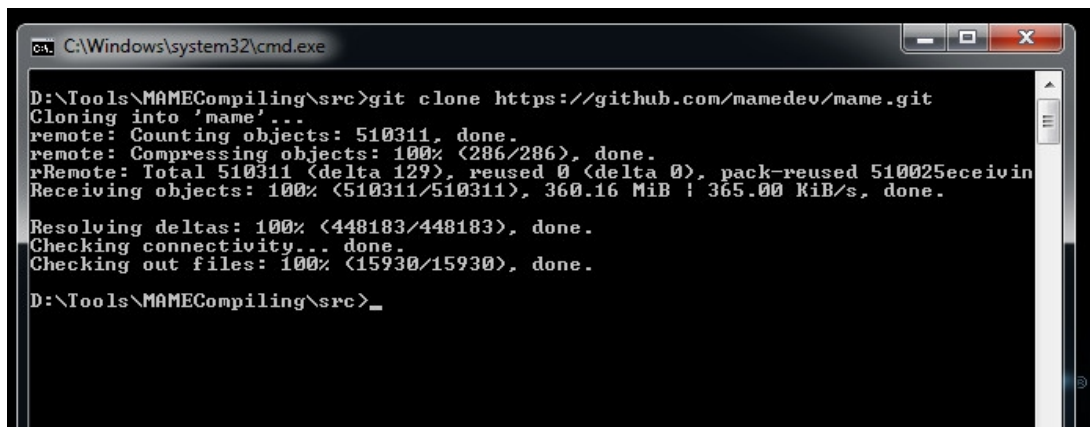

Change to the “src” folder. In that folder we want to download the source-code under “mame”. Execute this command:

“git clone https://github.com/mamedev/mame.git”

The “git” executable is able to download source-files from a repository. Option “clone” means that a 1:1 version should be created on our local drive (=full source code) and the second option is the address where the MAME source code is available.

After some minutes it has downloaded all source-files and has stored it under the folder “mame”.

! We can again download the full-source later when we do delete this folder “mame” and execute the above command. Be sure before you delete the “mame” folder that you have all custom script or needed folder removed from there. We are going to create some custom scripts and folder inside this “mame” folder in the next steps!

Here we are all source-files have been downloaded.

If you would like to update that source folder yourself from time-to-time you can execute the following command. Be sure that you are in the mame folder while execute it:

```
git.exe pull -v --no-rebase --progress "origin"
```

```
C:\Windows\system32\cmd.exe
D:\Tools\MAMECompiling\src\mame git.exe pull -v --no-rebase --progress "origin"

= lup to date1      ryan         -> origin/ryan
Already up-to-date.
D:\Tools\MAMECompiling\src\mame>
```

We have now compiled with the downloaded source-code from the repository. That was the actual build that is online. If you need the official latest version you have to download the full source from the MAMEdev site and extract it to this “mame” folder.

Compiling for the first time - MAME

Okay we have now our source-code available and we want to compile it to have all those exe-files at the end. We can do this by typing a command and we are lazy and before we start we save those commands into a cmd-file called “compile.cmd”.

```
make.exe clean
make.exe -j3 all
```

! First line will clean up the source before compiling (remove temporary compiling files). Second line will start the compiling. The ● parameters “-j3” does speed up your compiling when you have a dual core processor and the parameter “all” means with the tools.

- j3 → if your computer has a dual core
- jx → CPU core+1

>>> find more option in <http://www.gnu.org/software/make/manual/>

Ahhh I must extend our “updatescr.cmd” to save after an update the revision number to a file called “revision.txt”. Otherwise we have no information what revision-number the local source-code has ;-)

Add the following lines:

```
git.exe pull -v --no-rebase --progress "origin"
```

```
set /p Build=<.\git\orig_head
```

```
git rev-list %Build% --count >revision.txt
```

start another “updatescr.cmd”

```
D:\Tools\MAMECompiling\src\name>git.exe pull -v --no-rebase --progress "origin"
POST git-upload-pack (957 bytes)
remote: Counting objects: 68, done.

```

When compiling is done you should NOT receive any error and you will see all the created exe-files in this folder → then your compiling was a success.

We move now all created executables to a different folder (I do not let them inside the source-folder). Copy the revision number from the “revision.txt”.

Create a new folder under “src” called “Mame_builds”

Under “Mame_Builds” create a new folder called “0159r34076”.

At the moment the latest official MAME build is 0.159 and we have created a newer version with the revision number “r34076”.

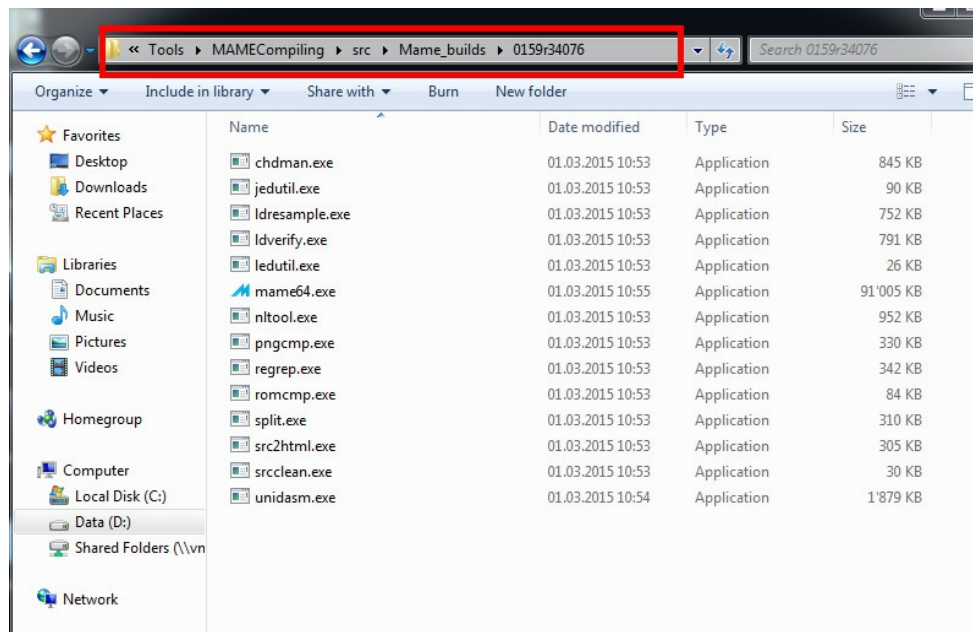

! Why are you not creating a folder name with the date? You could do whatever you like but it could also be possible that within a day
● after you have updated/compiled your build new changes have been made to the source tree!

Now move all created executable

..to this “0159r34076” folder.

Yeah great you have compiled your own executable for the first time.

! Be sure that you really do move only the executables to the “build” folder and nothing else.

Compiling for the first time - MESS

Okay MAME have been compiled, lets move on and compile MESS.

Create a new cmd-file called “compile_mess.cmd” and add the following lines:

```
make.exe clean  
make.exe -j3 all TARGET=mess
```

! First line will clean up the source before compiling (remove temporary compiling files). Second line will start the compiling. The parameters “-j3” does speed up your compiling when you have a dual core processor, the parameter “all” means with the tools and “TARGET=mess” will compile the exe for MESS.

After saving the file execute it :

After the compile NO errors should be displayed and the MESS executable have been created.

Copy the revision number (34076) from the “revision.txt” and create a folder “Mess_builds” in the “src” folder. Create a subfolder called “0159r34076” below

Move now all executable from the src/mame/ folder

...to the new folder “0159r34076”

You have now compiled your own MESS-executable for the first time.

! Be sure that you really do move only the executables to the “build” folder and nothing else.

! I will upload my batch-file that I'm using daily to mameguide.info. It has more options and is more advanced.

Updating source with TortoiseGIT (GUI)

MAMEdev compiling tools has everything included also updating the source-code with git.exe from the online repository. Sometimes it is better to have a GUI available for example to read the log-files what have changed in the code. I do recommend that you update your local source with the build-in function that git.exe does provide (see last chapter). But for those that needs it here is it “how-to” ;-)

Installing TortoiseGIT

Open a web-browser and navigate to :

https://code.google.com/p/tortoisegit/ tortoisegit - Windows Shell ... x

TortoiseGit - The coolest Interface to Git Version Control

TortoiseGit is a Windows Shell Interface to Git and based on TortoiseSVN. It's open source and can fully be build with freely available tools. TortoiseGit supports you by regular tasks, such as committing, showing logs, diffing two versions, creating branches and tags, creating new files and so on (see our [Screenshots](#) or [documentation](#)). You're welcome to contribute to this project ([help on coding](#), [documentation](#), [testing](#), [preview releases](#) or helping other users on the mailing lists is really appreciated).

Important notes

- There was a security issue in Git, see [here](#). [Git for Windows](#) < 1.9.5 is affected - so you should update. TortoiseGit itself is not (using the default configuration; only if libgit2 is manually enabled for checkout/fetching). TortoiseGit 1.8.13.0 includes all fixes.
- We would like to improve our website (i.e., built a separate one from google code). If there are any web designers out there who please contact sven@tortoisegit.org

Download & Install

The latest and recommended release of TortoiseGit is: [1.8.13.0](#), see [ReleaseNotes](#) for details.

[Download TortoiseGit](#)

[System prerequisites and installation howto](#)

[Git for Windows](#) 1.7.10 or above is also required for TortoiseGit (recommended order: install TortoiseGit first).

In the download section choose the x64 version to download.

Download

The current stable version is: **1.8.13.0**

For detailed info on what's new, read the [ReleaseNotes](#).

[System prerequisites and installation howto](#)

[Donate](#)

Please make sure that you choose the right installer for your PC, otherwise the setup will fail.

for 32-bit OS	for 64-bit OS
Download TortoiseGit 1.8.13.0 - 32-bit (~16 MB)	Download TortoiseGit 1.8.13.0 - 64-bit (~19 MB)

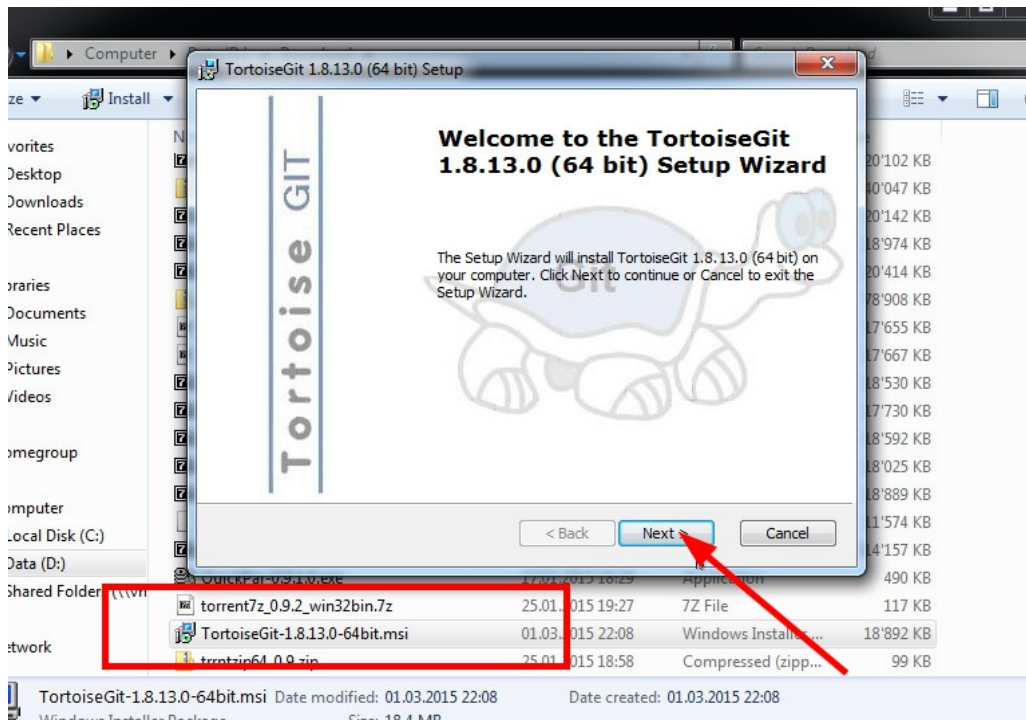

Before reporting an issue, please check that your problem isn't fixed in our latest [preview release](#). Also see [What to](#)

Save it to the download-folder

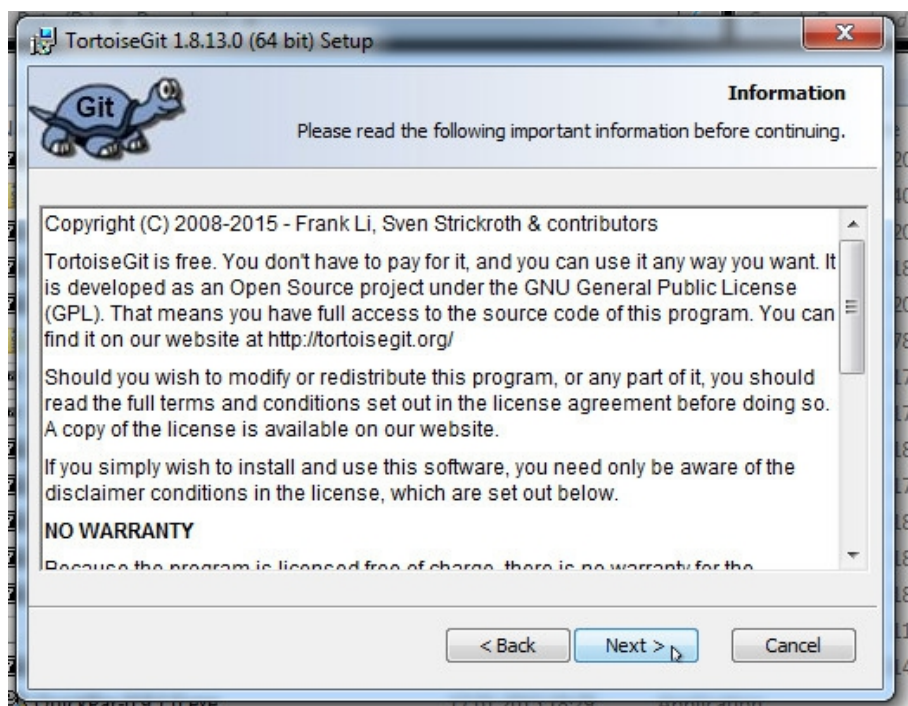

Start the installation

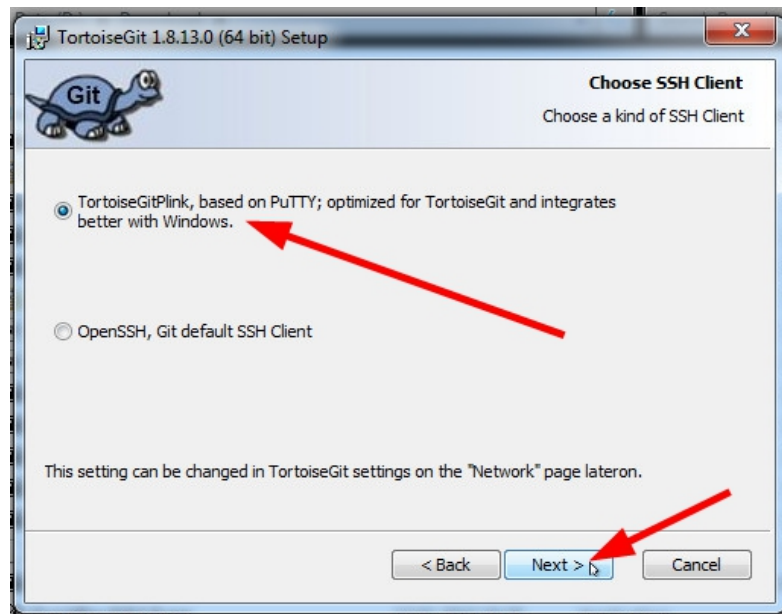

Read the information and click “next”

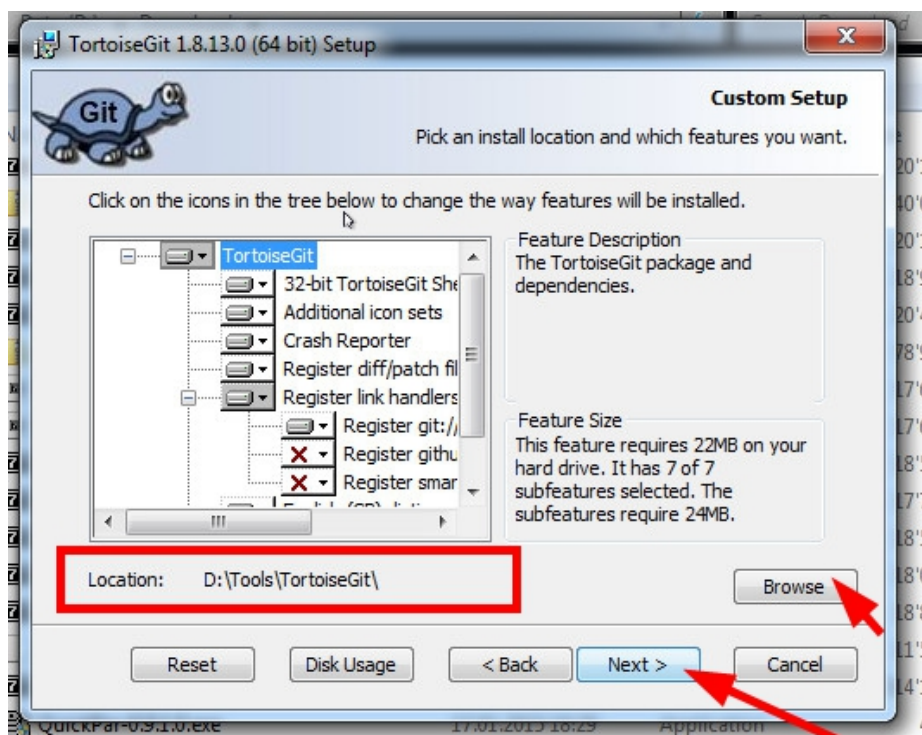

We leave the default choice and click “next”

Change the location where the program should be installed. The other Option we have not to change. Click “next”

Click “install”

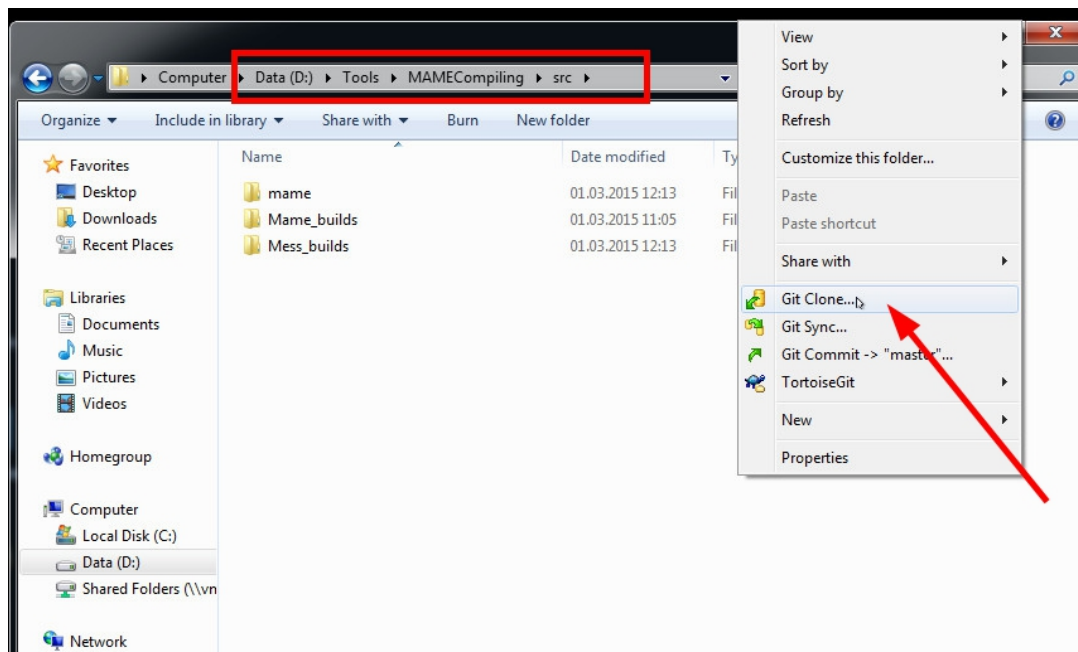

We have installed it :-)

Download full MAME source with TortoiseGIT

Go to our “MAMECompiling/src” folder and do a right-click and choose “Git Clone”

And if you have read on the webpage it does say that it TortoiseGIT needs “git” for function properly. That's why we receive this error message.

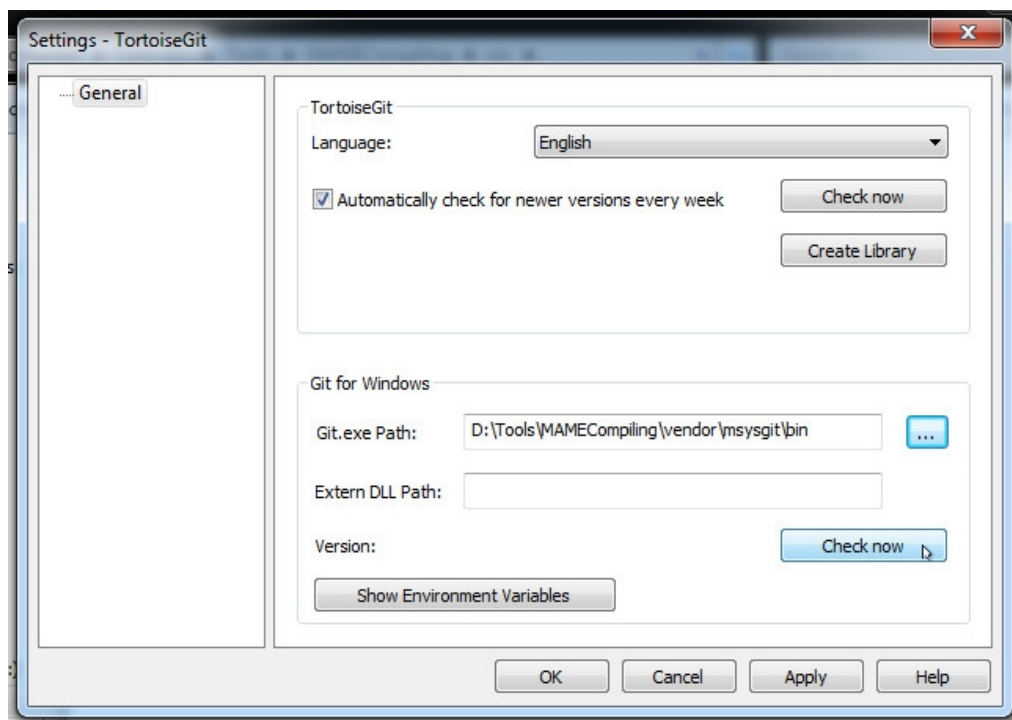

We click “Set Git path” (we have git already in our MAMEdev Compiling folder).

Set the “git.exe Path” to this folder where you have installed MAMEDev Tools:

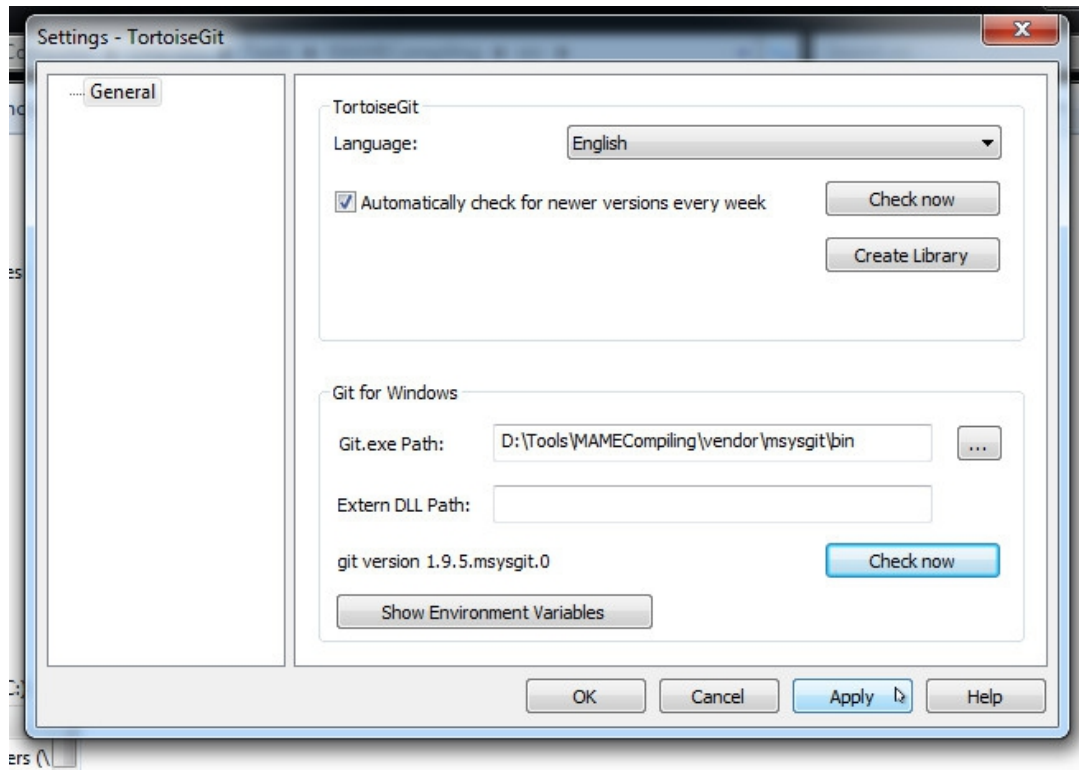

Click “Check now” and the version number should appears.

Click Apply/OK.

Now let's try it again.

Now a window should appear. We fill in the URL and point it to our destination:

```
git clone https://github.com/mamedev/mame.git
```

We do not click “OK” and cancel this operation here because we have already download the full-source code earlier. This was only to demonstrate how we should do it with TortoiseGIT ;-)

Update source with TortoiseGIT

We navigate into our “mame” folder. How does TortoiseGit or git.exe knows that this folder has the downloaded source-code? There is a hidden folder called “.git”. There are all information stored like what version has been downloaded and which local file have been replaced or edited. No worry we do NOT upload some files to the repository. It is also not possible when you have not an account there ;-)

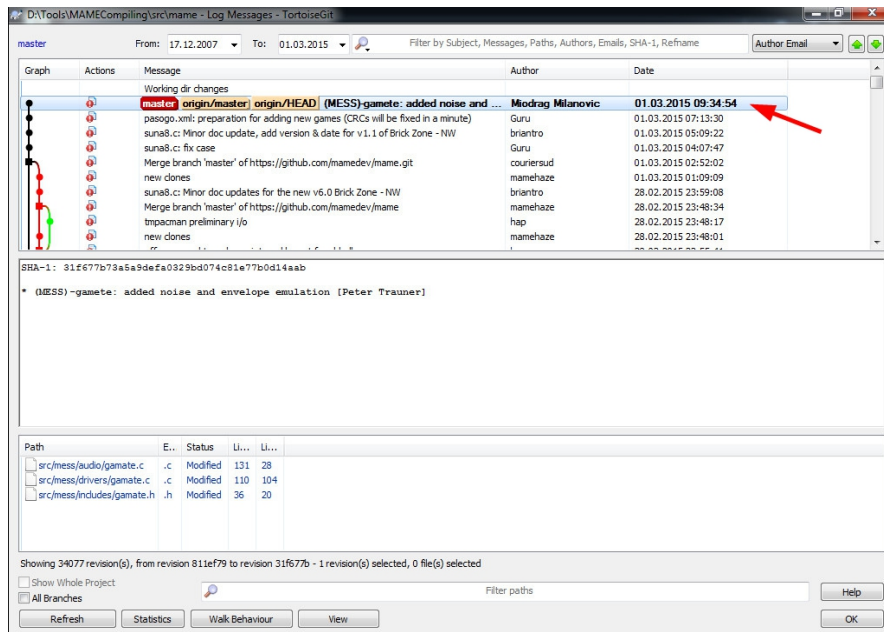

We right-click a free part of the folder and choose “Show log” from the context-menu.

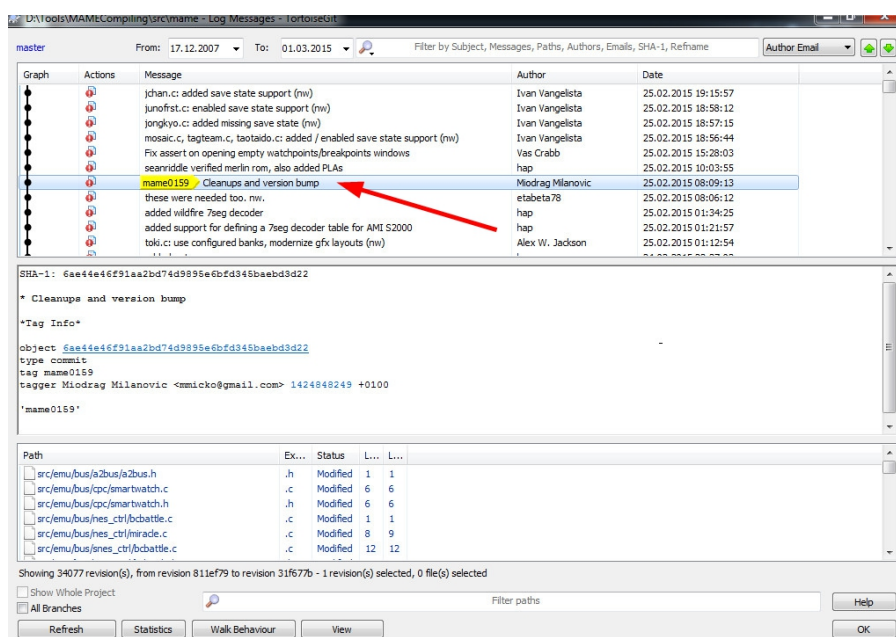

The Log-Browser is starting and does connect to the repository and reads the local “.git” information. It displays now the latest changes and you see in the bold line where your local source is (revision). In our case we are up-to-date.

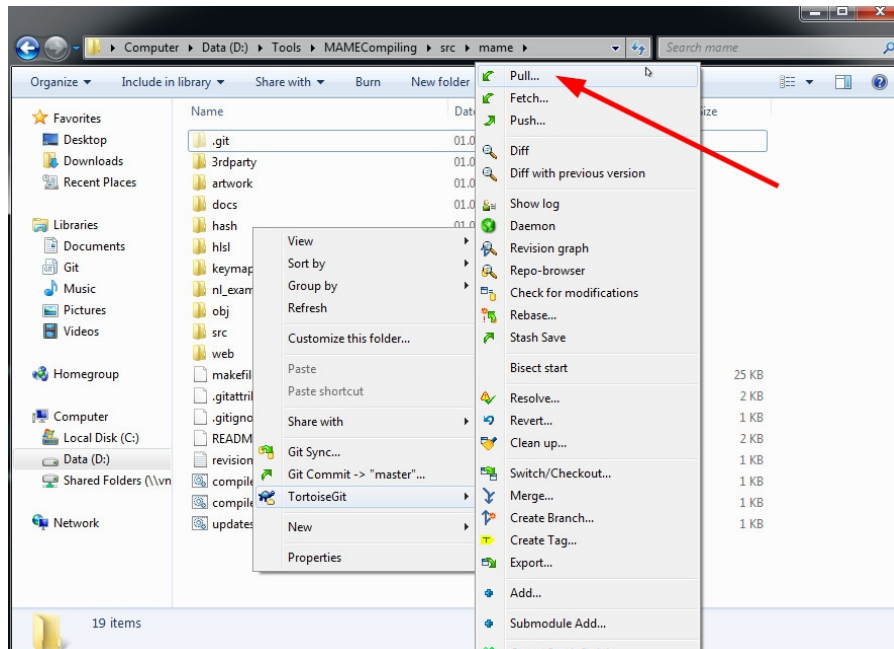

When you are scrolling down the changes you will find out where the official 0.159 version was compiled :-)

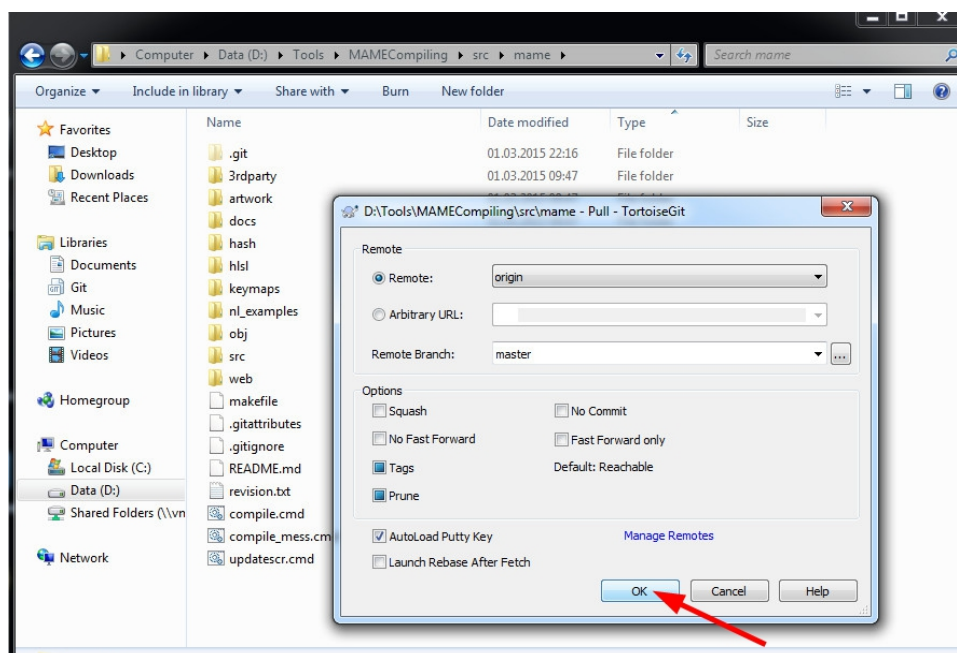

For doing an update to the local source-code you have to execute “pull” from the context-menu

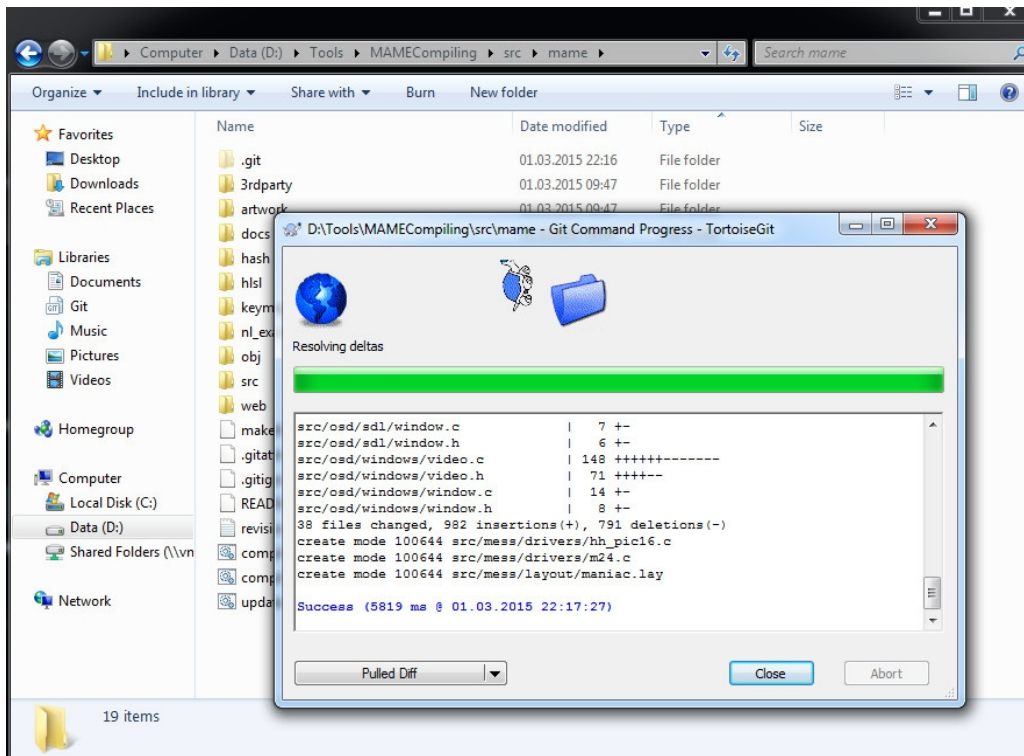

A new window is opened. Let everything as it is and start the update process with “ok”

hmmmm it seems that in the meantime a new change was added ;-)

We have now updated our local source-code with the latest from the repository.

Something we can not do here → I have not found out how we can calculate the Revision-number we have done in our cmd-file :-)
